ARTIFICIAL FECUNDATION AND POSITION DURING COITION.

BY DR. LUTEAUD,
PARIS, FRANCE.

(From advanced sheets furnished exclusively to the Times and Register, by Thomas Linn, M.D.)

GENTLEMEN: Artificial fecundation had been tried on the inferior animals during the century before this, but Swammerdam and Roesel did not have any success with it, and it was the naturalist Spallanzani, in 1767, who made the first successful experiments in dogs. The prejudices of that time prevented him from trying it on man, although he several times expressed his belief that it was possible to produce fecundation in human beings as well as in animals. The first success in man we know of was made by Hunter, in 1799. The famous surgeon gave a consultation to a man who was afflicted with hypospadias, and wished to become a father. He was advised to inject the sperm, which he could only deposit in the vagina, and the injection was followed by a complete success. Girault gave the first authentic cases of artificial fecundation; which he obtained by injecting the fluid into the uterus, using a urethral sound and blowing the sperm through it. In 1869, he published twelve observations, the first of which dated from 1838; twenty-seven injections were made in all and only two cases failed, while none of them had any complications. Marion Sims, in 1866, related a case of success, and the same year Gigon published a thesis on the subject with several observations. In 1871, Courty gave a short account of the operation, and Professor Pajot now recommends it. He thinks it is advisable, *after all other means have failed*, and he proposes for the operation a new instrument, which he calls a "*fécundateur*," (which consists of a gutta percha sound terminated by a little sack or ampulla). Pajot advises artificial fecundation not only in the case of malformation in man, and in uterine deviation in woman, but also in sterile unions, where the spermatozoids are not found imperfect or wanting. Leblond, in his treatise on gynecological operations, gives this operation; so that it may be said, in fact, that all the classical authors admit its performance. Dr. Luteaud believes, with Pajot, that it is only to be tried after all other methods have failed. This is a fundamental point, but it is to be asked, all the same, if it might not be advised before performing amputation of the os, which, if it does not constitute a real danger to life, still is a traumatism that has certain dangers. This question may be left to a certain extent to the person most interested. There are women who prefer an operation to simple injection into the uterus, owing to the shock given to their modesty, which is perfectly legitimate, but these remarks do not apply to those cases where the operation of amputation is advised for other reasons than simple sterility.

It is understood that artificial fecundation is not to be attempted *after the meno-pause*, and it is also contra-indicated in cases of malformation of the pelvic

or genital organs in woman, and again in atrophy of the uterus. The existence of chronic pelvi-peritonitis gives but little chance of success, and again metritis and endometritis, with all the inflammatory uterine troubles, will prevent conception, unless they are treated and cured first of all. The operator must be certain that the fecundating fluid contains spermatozoids, for while we know but little of the pathology of these corpuscles we do know that sperm without them is useless; the microscope must then be used first. Then there are several *moral* considerations for the physician to consider. If there is a tubercular, cancerous, or even scrofulous diathesis present in one or both of the parents, ought he to advise progeny? No! Nature herself often refuses in such cases, as there may well be imperfect beings created. A first condition of success is that the menstrual molimen exists, and as said before, that the spermatozoids are present, while no malformation opposes conception and delivery. Modern physiological researches tend to prove that fecundation in women takes place before the menses rather than after the period, so that it is advisable to attempt artificial fecundation during the three or four days before the menses are expected; then, if there is a failure it can be tried again during the week after the period.

As to the method of operation: A large number of plans have been proposed, but only those will be mentioned which are compatible with the dignity of a physician and the modesty of woman. Marion Sims's operation is well known in America. It consists of an injection with a glass syringe with a rounded bulb on the end, and he insisted that only one drop be injected, as he feared that the uterus would contract and expel any larger quantity, but it has since been found that the uterus will retain two or three drops. Courty's method is something the same, except that he collected the fluid by advising the use of a condom cover to retain it. Professor Pajot's method consists in a syringe arranged to collect the sperm by aspiration and injecting it into the os some two or three centimetres. He first used the touch to find the os, but now operates *de visu*. Four or five attempts are as many as it is worth while to try, these to be done at the menstrual periods as mentioned. Any physician who is accustomed to passing a sound into the uterus, can do it. The most important point is in regard to the cervical canal. The operator must assure himself that it is permeable and also see what its direction is, so that at the last moment he will not have to lose time. This information should be secured some time ahead, and it is also well, beforehand, to institute a treatment of the vaginal mucous membrane. It is now well known that the vaginal secretions are often acid and that this condition is almost surely destructive to the spermatozoids. So that a treatment by alkaline injections should be commenced a week or more beforehand. M. Luteaud recommends a solution of nitrate of potash (1–1000) morning and evening injections. The husband must be advised to abstain for a certain time, so that the quality and quantity of the secretion will be secured. A basin is prepared with hot water (40°, centigrade) and a Ferguson speculum with a special form of intra-uterine sound is placed in it. Then the moment the coition is over, the operator is introduced, when by *Luteaud's* method, he simply passes the speculum, which collects the liquid by pushing it towards the os uteri. The special sound is then introduced with a rubber bulb on it, a few drops of the liquid is aspirated, and at once injected into the uterus. A small vaginal tampon of borated cotton is passed, to be left against the os for a few hours, and the patient is advised to remain in bed during that time.

M. Luteaud gives his statistics. He practiced artificial fecundation in twenty-six cases, in women from twenty-seven to thirty-nine years of age He only claims relatively little from it, for he had only two cases of entire success; besides one of hypospadias, and two other cases of incomplete success, where there had been conception produced, but abortion came on within three months. At the same time he feels that it is an operation that should be advised in the cases mentioned.

Position during Coition.—Dr. Luteaud concludes his lectures by some practical considerations on coition, which, as he says, is an impetuous act accomplished under the influence of an instinctive impulsion, without reflection, and in certain cases a physician should study the conditions under which it takes place so that he can give the interested parties good scientific advice that may allow them to succeed in the reproduction of the species. This result can sometimes be attained by a careful study, based on physiology and on the situation of the organs in the female, which are often so modified, that it is difficult if not impossible for the sperm to penetrate the cervical canal. The object of coition, practiced for fecundating purposes, is to introduce sperm into the uterus, or at least, to *project* it against the os uteri: and a doctor, consulted by a sterile woman, should inquire if coition has been so practised that that object could be obtained. He should also examine if the male organ is properly formed, if the os uteri is in the axis of the vagina, and if there are no false vaginal passages. Finally, he should see if there are not certain positions or attitudes that he could advise in the case given, that would produce the result desired, that is, to place the organs under the most favorable conditions for fecundation. Certain defective male organs are more frequent than we think (epispadias and hypospadias), and the physician should always examine the husband. Pajot has often insisted upon the *false routes* that may be created in the vagina, owing to deviations of the uterus, or to a conical disposition of the os, and, above all, to a hypertrophy with elongation of the uterus, which allows the male organ to penerate into one of the vaginal *cul-de-sacs*. The sperm is then destroyed by the acidity of the secretion, and conception is prevented. This goes on, for coition being usually performed in a uniform manner, the false route becomes a permanent one, and becomes a cause of infecundity that only increases with time. Uterine deviations are the principal cause that most often places the mouth of the organ out of the axis of the vagina. These are so well known that it is useless to describe them, but it is well to inquire if it is not possible to remedy these defective conditions by advising *certain positions dur-*

ing coition, which may bring the glans penis in more direct contact with the os uteri.

In the human species sexual intercourse takes place, as a rule, in the *dorsal decubitus*. The vertical transformation of man, which has taken place so gradually, did not, however, allow any extra accommodation to the uterus for the present upright position of woman, and the organ keeps the identical situation that it has in monkeys and other quadrupeds. It is normally in anteversion, and forms an angle with the vagina, which makes a most unfavorable condition for fecundation, according to the method of coition as practised by our race. It results from this, that the position *more canum* is the most favorable one for conception. This is confirmed by clinical experience and by a mechanical study of the organs. One has only to place a patient in the genu-pectoral position and apply the Sims' speculum to see how easily the os is reached in such a position. Not only is it more accessible, but it also changes the situation so that it, for the moment, at least, cures the retroflexion and the vaginal false passages that may have existed.

It is, therefore, well to recommend the position *more animalium*, above all in cases of retroflexion. Hegar also advised the husband to raise up slowly the abdominal mass, and let it go suddenly at the end. No matter how repugnant to the feelings of a woman such advice may be, it is certain that such is the desire of sterile women to have children that they will gladly submit to the modification of position; few but those who have had experience of it can understand the intense desire they have for maternity. M. Luteaud states that the female seated upon the male during coition brings the organ also into the same favorable position, and has the advantage of allowing the position to be kept for a time *post-coitum*, which is favorable for conception. Dr. N. Guéneau de Mussy advised the husband to practise certain manipulations to facilitate the entrance of the sperm into the canal of the uterus.

Sed aud illicitum mihi visum est, si post diversatentamina dicitius uxor infeconda manserit, ipsum maritum digitum pos' coïtum in vaginam immitere, et ita receptum semen uteri ostio admovere. Et cum ostiolo uteri hœret, ut in pervium canalem, spermatozoïdum motibus faventibus, prodeat sperare non absurdum.

These Latin directions may be useful in certain cases, but they would first require all husbands to practice the touch and be able to recognize the os uteri. Prof. Pajot advises women who have anteversion to *retain their urine* for some time before coitus, and when there is a retroflexion he brings on constipation, to fill the lower intestine and throw the uterine mouth forwards. In lateral versions the position on the side can be recommended.

In regard to the most favorable time for conception, M. Luteaud advises four days before and one week after the menstrual period; but he says that it cannot be contested but that it takes place at all times of the month. He also is inclined to believe that frigidity or a passive action in women is an obstacle to fecundation, and that the orgasm in them is useful for conception, but not actually necessary, for it cannot be denied that the conception takes place without it. But both complete erection and spasm opens the cervical canal and leads to the desired object better than passive action on the part of women.

AUTO-INOCULATION IN TUBERCULOSIS.

By LAWRENCE F. FLICK, M.D.,
PHILADELPHIA.

EVERY physician who has had any large experience with tubercular diseases has no doubt frequently asked himself the question, why do my patients suffering from tuberculosis take relapses? By the use of the many modern resources of treatment he usually succeeds in getting most forms of tubercular inflammation to temporarily improve and some forms to get well. Where the tubercular inflammation is external and entirely within reach of mechanical interference, he is, indeed, master, and can always cure; but where it is beyond his reach, his best efforts are attended with uncertain results. In tubercular enteritis and pulmonitis, for example, his patient will improve under careful treatment, and just when he has arrived at that stage where he promises ultimate recovery, without any understandable cause he takes a relapse. The people say he has taken a fresh cold, and the physician, for want of a better explanation, says so, too. A somewhat careful and studied observation of the phenomena has convinced me that they are not the result of taking cold, but of auto-infection. I will relate one or two cases which had something to do with bringing me to that conclusion:

M. Q., a young lady, came under my professional care about five years ago. She had been running down lately and was developing a cough. Physical examination revealed a tubercular deposit in the apex of one lung. With a few months' treatment and a trip to the country she apparently recovered. A year later she came back to me with all her old symptoms in an aggravated form. There was not only tubercular deposit, but the beginning of softening. Prolonged confinement to bed, with nutritious diet, again arrested the disease. With summering in the country and wintering in the house, and such other treatment as was from time to time indicated, she again apparently recovered after two years. She was, however, left with an immense cavity, which, in spite of all treatment, continued to secrete some pus. She disappeared from under observation for about six months, when she one day came to my office saying that she had recently not been feeling so well, and that she was again running down. A physical examination showed both lungs to be studded with tubercular deposit. She went down rapidly, and is now in bed in a dying condition.

A. E., male, aged fifty-three years, was taken down with what was supposed to be pneumonia. After the acute symptoms had passed off he was left with shortness of breath, night sweats, profuse expectoration, and rapid emaciation. Physical exami-

nation revealed a condition of the base of the left lung which is usually called chronic pneumonia. After about six months' treatment he was very much improved, so much that he himself thought he was near enough well. Physical examination, however, showed that there was still tubercular deposit with the inflammatory condition which accompanies it in the base of left lung. He remained in this improved condition for about six months. Suddenly he again began to lose flesh, and to develop all the symptoms of acute phthisis. Cavities formed in the apices of both lungs, and in a very short time he died. A post-mortem examination showed the base of the left lung to be riddled with small cavities.

J. F., male, aged about thirty years, good family history, invited a consumptive friend to spend the first week of November with him. For some reason or other he took him into his own bed. Toward the end of November he was himself attacked with acute tubercular inflammation of the apex of the right lung. The symptoms were quite acute, but after several weeks' treatment began to subside. The cough grew less, the sweats ceased, the surface of inflamed lung diminished, strength returned, and the patient began to gain flesh rapidly. So favorable did everything look that I had great hopes of curing the case. Quite suddenly the improvement ceased, vomiting set in, the strength began to fail, the appetite, which had been excellent, changed places with anorexia, and the case took a rapid retrograde turn. Because of the vomiting, I suspected a new deposit of tubercle, and repeated examinations brought it to light in a few days. Not only was the inflammation extending down the upper lobe of the right lung, but a tubercular deposit was taking place in the middle lobe of the left. The patient was confined to bed, from which he may never again arise.

In these and other similar cases there was no exposure that could have accounted for the sudden change of the course of the disease. In none of the cases did the change come in extremely cold weather, and in one it came during the summer. Taking cold, moreover, would not satisfactorily account for the phenomena, as in each case there were new centres of disease, and taking cold should only have affected the old centre. Auto-infection not only gives a proper explanation of these and all similar cases, but renders intelligible many clinical facts about phthisis which are otherwise hard to understand.

Were it not for auto-infection I believe that most cases of tuberculosis, at least most cases in which the disease is outside the cranium, would get well. In every case which has ever come under my notice there was a decided effort on the part of nature to establish a cure, and in proportion as the victim had retained his powers of digestion and assimilation she made a good, bad, or indifferent struggle against the disease. In her very effort, however, seems to lie the danger, for by trying to resolve the tubercular deposits, she is liable to start up new centres of disease.

The theory of auto-infection not only explains to us why certain methods of treatment are successful, but points out to us the direction in which we have to look for the cure of tuberculosis. Out-door life and nutritious food have always been looked upon as the most useful measures in the treatment of consumption, and they have been useful because the former affords a partial sterilization and the latter enables the system to better combat the disease.

It is to sterilization that we must look for the means of curing tuberculosis when it is beyond the reach of mechanical interference. Nature is always able to repair the damage resulting from the presence of a foreign body, but in many cases of tuberculosis she seems to be unable to prevent the reproduction and colonization of the bacillus. Whatever will enable her to do this will help to cure tuberculosis.

736 PINE STREET.

A CASE OF ABNORMAL DEVELOPMENT.

(Read before the Leavenworth Medical Society, February 25, 1889.)

BY W. D. BIDWELL, A.M., M.D. (Harvard),
LEAVENWORTH, KAN.

DECEMBER 30, 1888, I was summoned in haste to attend a boy, who had accidentally shot himself in the neck.

On the way to the house I ascertained that Hugh C., had surreptitiously obtained possession of a 32-calibre revolver belonging to one of his father's tenants. His mother called him into the house, and being unwilling that she should see it he threw the revolver from him and it was discharged, the ball entering the neck a little over an inch and a half to the right of the median line in front and at the level of the cricoid cartilage, ranging upward and backward and emerging at the margin of the hair about one inch from the median line behind.

The hemorrhage was very profuse, and I fully expected the boy to bleed to death before I arrived. He was very faint from loss of blood, pulse 160 and weak. Removing his clothing, I made as near an approach to an aseptic dressing as was possible and had the boy supplied with all the iced milk and water he wished. He spit up no blood, but his breathing was quite labored. A subsequent rise of temperature with marked œdema of the neck led to drainage, and hot applications and antiseptic dressings were followed by a speedy recovery.

But the chief interest centres in the boy himself, not in the wound. Both his father and mother had been married twice. Mr. C., now fifty-six years old, had ten children by his first wife; of these three did not come to full term. One girl died at one year old, one at seven, and two boys, aged four and nine. Three children are still living; a son, aged thirty, and two daughters, aged twenty-six and twenty-eight. Mrs. C., now forty-nine years old, had four children by her first husband, all girls. Three died at the ages of four months, two years and three months, and seven years three months; one daughter now living is twenty-five. Mr. and Mrs. C. have been married twelve years and have five children; a boy eleven years old; a girl nine years old; Hugh, five years old, and a twin boy and girl three years old.

All of these children have been well formed and developed naturally except Hugh. At birth he was very large and strong and was estimated to weigh between

twelve and fourteen pounds. He has always appeared old in his ways and took kindly to men and boys, but would have nothing to do with girls or women if he could avoid them, even shunning his mother and sisters. He began to cut his teeth at four months and had them all before he was a year old. Began to walk and talk a little at fourteen months. When nearly 2½ years old he had a severe attack of whooping-cough followed by measles; for four months he was up and down and during two months was apparently about to die and lay helpless in the cradle. At about the middle of this sickness he had a spasm, the only one he has ever been known to have, followed by four passages of blood from the bowels; and when his mother changed his diaper at this time she noticed that the testicles were enlarged and thought the boy was ruptured, a belief shared by the attending physician for some time. After this spasm he had fainting spells and seemed to be at the point of death for two or three days, but recovering enough to talk, it was noticed that his voice was changed and hair appeared upon the pubes. During the last year he has been subject to erections and seminal discharges, and now, at the age of five years and two months, his condition is as follows:

Height, four feet three and a half inches; waist measure, twenty-eight inches; weight, eighty-two and a half pounds; circumference of head, twenty and a half inches; neck, twelve one-quarter inches; biceps, nine inches; calf, twelve inches. Hair of head very thick and black, eyebrows almost meeting and quite heavy, downy moustache at least three-eighths of an inch long, a few hairs under the arms and about the nipples, heavy growth of hair on the pubes, penis and testicles the size of those of most boys of seventeen or eighteen years, body and limbs plump and well developed, voice a deep bass, face apparently thirteen or fourteen years old. Mentally he is still a child, bears pain bravely, is fond of dogs, horses and fire-arms. He enjoys being with men and seeing them work, yet enjoys infantile toys. Avoids women, not allowing his sisters about his bed, even when he is sick. Is very headstrong, yet has listened to and obeyed rigidly all directions of the reporter. He has twenty-four teeth. He has been even heavier than he now is and presents the general appearance ot a chubby, bow-legged boy of twelve or fourteen, somewhat deficient mentally.

In the "Reference Handbook of the Medical Sciences" fourteen cases of early puberty are mentioned, six of which are in boys. This is the only account I can find in my library, but undoubtedly such cases occasionally appear and are not reported, as in this case the condition was known by another physician for two and a half years.

Such cases are, however, few and far between and interest us only as curiosities or freaks of nature.

I have been asked concerning the probable future of the child, but having no data to go upon I should merely say as a guess, that his mental condition is likely to keep about even pace with others of his age, but he is likely to show signs of senility earlier than the majority of men.

Of the six cases referred to above:

No. 1 showed enlargement of the sexual organs at the age of twelve months and died when five years old showing signs of premature senility.

No. 2 is not described at all.

No. 3, at three years of age, had enlarged organs, seminal discharges, the voice had changed in pitch, was three feet six and three-quarter inches in height, and weighed fifty pounds.

No. 4 was very large at birth, with hair like that of a child five months old, hoarse voice, prominent pudenda. From four to fifteen months, penis enlarged till at the age of three years, when flaccid it was three inches, when erect six inches. He was then three feet and seven inches heigh and weighed sixty-four pounds.

No. 5. Not described.

No. 6. At twelve months, change of voice and generative organs, hair on pubes. At three years was three feet four and a half inches tall; weighed fifty-one and a quarter pounds; waist measure, twenty-four inches; measure of cranium, twenty inches.

AN ENORMOUS MULTILOCULAR OVARIAN CYST SUCCESSFULLY REMOVED.

(Read at the Philadelphia County Medical Society.)

By WILLIAM S. STEWART, M.D.,
Professor of Obstetrics and Clinical Gynecology in the Medico-Chirurgical College.

MR. PRESIDENT AND GENTLEMEN: I am desirous of describing a recent operation, on account of the enormous size of the tumor and the highly satisfactory results of its removal.

Mrs. D. J., aged thirty-eight years, of Camden, N. J., was brought to my office in the fall of 1888, by her physician, Dr. W. H. Ireland.

The history of the growth and the examination made at that time convinced me of the presence of a multilocular ovarian cyst. During the six months following the patient was not seen, but the tumor continued to grow very rapidly until she was no longer able to endure it, and at last requested its removal.

Having made all of the necessary preliminary preparations as to the room, bedding and the patient herself, I performed the operation on April 10, 1889, being kindly assisted by Drs. W. H. Ireland, Palm and Ralston. It was with great difficulty the patient could lie on her back owing to the weight of the mass and its encroachment on the diaphragm. Respiration being very much embarrassed during the administration of the anæsthetic we were obliged to proceed with the operation in the most rapid manner, giving alternately hypodermic injections of whisky, digitalis and strychnia.

On reaching the cyst and penetrating its outer walls the previous diagnosis of its multilocular character was confirmed; but so exceedingly vascular was it, apparently more blood than albuminous liquid being poured out, in alarming quantity, it was thought best to desist from any further attempt to empty the many cysts of their contents. The abdominal incision was at once enlarged, and having separated with my hand the numerous adhesions of the cyst wall with the parietes of the abdomen and the internal viscera, the huge mass was lifted from its situation in the abdomen and

pelvis, drawn through the abdominal opening and left resting upon the pubes and thighs of the patient.

Another difficulty encountered was the ligating of a short and exceedingly thick pedicle. We succeeded in transfixing it with a double ligature of plaited silk, which was applied as firmly as possible, but on severing the pedicle it was found necessary to lift two arteries on the stump and secure them by extra ligatures. For a time there was considerable oozing from the various points of adhesion; but by the use of hot sponges the hemorrhage was checked, and no additional ligatures were applied.

The time occupied from the first administration of the anæsthetic till the removal of the tumor was one hour, during most of which time the patient was in an apparently lifeless and most critical condition. After thoroughly irrigating the abdominal cavity with warm water, the seven-inch incision was closed with sixteen sutures, a drainage tube being left in. No unfortunate symptoms have been shown to the present time (fourteenth day).

On the fourth day the drainage tube was removed, and on the eighth, half of the sutures; each alternate one being allowed to remain two days longer as a safeguard against gaping of the wound. Being of silkworm gut they are entirely unirritating.

The tumor was weighed shortly after its removal, the solid mass itself holding the beam of the steelyards on a level at eighty pounds, whilst the liquid that escaped was estimated by all present to have been not less then ten pounds, making in all a mass weighing ninety pounds.

PHYSIOLOGICAL MORALITY.

(SOME FIRST PRINCIPLES.)

A CONTRIBUTION TO SOCIAL SCIENCE AND PREVENTIVE MEDICINE.

By FRANK S. BILLINGS, M.D.

[Concluded from page 393.]

WHILE the functional activities of the child's brain are, in reality, thus limited, the limits are of such a nature, in the normal child, that they are never attained. They will answer all the demands which can be made upon them, but the nature of the result will ever be dependent upon their anatomical structure and the physiological condition in the centres of these activities. We cannot make children what we will. The child has more rights than the parents. Intelligent parents will learn to respect them. Nature determines them.

Why one child is determined to be, or do, one thing, and another something else, as a means of livelihood, against the wishes or will of its parents, is neither dependent upon pure cussedness, as is too frequently assumed, nor upon any especial influence hypothetically exerted by his Satanic majesty, or some of his agents, nor upon obstinacy or ill-will, but rather upon fixed and unchangeable anatomical and physiological conditions in the child's brain; the cause of which, or the rudiments of which, were present at or long before its birth. The parents are more frequently to blame for them than the child.

The more decided such idiosyncrasies are marked, the greater the task of the parents. If of a proper nature, the greater the character will be of the matured individual. Such conditions in children are too often the result of the incompatible and inconsiderate marriage of the parents.

I have in preparation a paper upon marriage from the historical, social, and physiological points of view, a few of which I desire to just touch upon here.

Marriage is the most momentous act in the drama of civilized life, because *bound with it is the creation of other men or women who may be innocently cursed or blessed by our act.*

While we have been differentiated, under certain exact physiological laws, into males and females for the continuation of our species, it must not be assumed that marriage is or was a necessity thereto.

Maraiage is an artificial institution, the result of social necessities.

In the early days of our species, and in quite a number of aboriginal races to-day, the institution of marriage did not, or does not exist.

Even in its crudest form the institution of marriage implies that mankind had found that indiscriminate and unregulated intercourse seriously interfered with the welfare of society. The "struggle for existence," as soon as it makes itself felt, leads to some sort of restrictions upon the production of children, and to the elucidation of some regulation by which the producer shall be made more or less responsible for the object produced until the latter is able to provide for and protect itself.

We must admit, to the disgrace of our species, that it does not multiply by the intelligent action of its individuals, nor by instinct and fixed law as is the case among the lower animals, but, in general, through the accidents of lust.

Here, again, man can distinguish himself from the other species of the animal world, *if he wills. He can be an intelligent actor in the phenomena of procreation or not, as he wills.*

Man has acquired this ability. In the majority of cases he gives no evidence of possessing it, however. Our race is increased more against the will of the chief factor in its production—woman—than with it.

Common sense, common decency, and due regard for the child, indicate that it should be a law in every family, that no more children should be produced than parents have the means to take care of until the child, or children, is, or are, able to take care of it, or themselves, even should both parents die during the minority of the child; or rather, to take care of it until it is fifteen years old.

Man has no right to gratify his passions at the expense of the community, and far less at the expense and misery of the object produced.

The above are not meant as restrictions upon marriage, but are regulations which should prevail in every family for the good of all concerned.

Marriage is, generally, the most unintelligent act which humanity performs. It is entered upon utterly regardless of the probable result.

As conducted, it is dependent upon a pretty face, a handsome form, and a replete pocket; three very essential factors, I admit, but the one great essential

is rarely considered, viz. : *physical fitness in both contracting parties to "multiply and replenish the earth."*

Lust and sensuality are looked upon as necessary concomitants and manifestations of love, when they have no possible connection with it, as is shown by many experiences which shock the moral element in society. The first two satiated, the hypothetic love leaves the home and its obligations, to seek sensual satisfaction elsewhere.

Physical fitness for the responsibilities assumed, financial fitness, to a certain degree, to carry them out, should be demanded by social law, if it has in mind the well-being of society, before men and women could marry.

Respect for each other's intellectual abilities, an interest in what interests each other, mutual respect for one another, are the other chief essentials to married happiness.

These attributes will generate a true love which will endure when all bodily enchantments have begun to wither, and which will burn the brighter as the animal fires flicker out with the increasing years.

Such a marriage should prove a blessing to the child produced. But that it may, it is necessary that parents should have a better and more exact idea of their natural relations to the child and of the *rights of children.*

Even these have their exact anatomical and physiological foundation.

We can only touch on a few principles in concluding this somewhat lengthy introduction to a grand subject.

In every child, soon after birth, the elements of the character centres in the brain begin to assume a certain fixity of form, position, and relation to one another; which, under normal circumstances, gradually increases in character with the years. That is, as these conditions become more and more solid the character of the child manifests itself more and more strongly.

This anatomical and physiological fixity in these brain-centres gives occasion to the intellectual idiosyncrasies of the child. They are its character centres. Its abilities and weaknesses have, therefore, a fixed structural foundation. Their causes existed before the child becomes such, or even before it was conceived, in many cases, in similar conditions in the parents or its ancestors.

These character centres are the pole, the centre, around which the entire personality of the individual is to revolve during life. Their careful development is the ultimate end of the science of parentage. Parents and teachers should study the developing phenomena by which these character centres manifest themselves to their observation. *They are the "magnetic needle" which nature places in each child to indicate to parents, guardians, or teachers the course that should be pursued in the education of the child.* The child will soon indicate some abilities in one direction more than another. Many parents say that "they cannot see this." The trouble is, they do not try to see it. They are indifferent to it. The child is theirs. Others do not know enough to seek it. This is the majority. They have not been properly instructed. They are not educated. The same is true of those growing up to be the parents of the next generation. Their teachers know nothing. Their parents know nothing. They know nothing of the great laws of life and their phenomena. Talk about our universities, our medical schools. Bah! The teachers in them have not learned the primary lessons in biology yet. They are not even primary schools of real instruction. They can cultivate fairly. They cannot instil the first principles of education. Free thought, honest thought, is not countenanced in them. The curse of the theological god rests on them. Theological ignorance rules in them whether it be admitted or not. They are fair asylums to bring up intellectual infants in. The teachers are fair intellectual nurses. They are poorly equipped to fit men and women to fight the battles of life according to law.

Parents must learn to seek this "Lebens-punctum" in their children. Having found it, every endeavor must be made to support it by the broadest education possible, while this special point must be developed in every available manner.

The work of the science of parentage is to fit the child to take care of itself in the struggle for existence of its mature years.

More gifted children have been spoiled through the ignorance and obstinacy of parents than have ever been blessed by them.

The advancement of the world has been checked by the ignorance of parents of every principle of the science of parentage.

More children have been cursed to a life of unsuccessful misery by that accursed puritanical family law "that a child should be subject to the will of its parents," than have ever been blessed by its other precepts.

No child is the property of its parents, to be bent to their wills; to be subjected to their stupid ignorance.

The very constitution of this country flatly denies any such doctrine.

The child is a distinct individual, with its own individual rights; with a developing will which must be respected as its peculiar and inherent right, but which must also be most carefully studied, guided and directed, that the lesson of self-control may be gradually learned, so that it may be well fitted for the work of life.

The child is to be directed, not controlled by parents.

The gradual development of the will of the child in right directions is one of the chief duties of parentage, and leads to the formation of the first principles in the education of the child.

The child is not to be controlled by parents. It is rather to be guided until, by the development of its own intellect, it gradually becomes able to distinguish between a right and a wrong peculiar to itself, and acquires some accurate ideas of the relation it bears to the outside world, as well as the relation of each part of its body to the other parts of the same unit. The right and wrong of an educated intellect must gradually take the place of a conflict between (to the child) *non-comprehended forces, within itself, and the will, it should be the matured judgment, of its parents.*

The child must learn to trust implicitly in the superior abilities and judgment of its parents as a saving power, until its own intellectual forces have been sufficiently

developed for it to stand upon its own knowledge. This can never be attained in families where that other accursed Puritan principle prevails, viz., "*to spare the rod is to spoil the child.*"

It would generally do the parents more good than the children!

This is the end. It is, has been my endeavor, to place before you as many physiological principles as possible without giving the detailed evidence, in order to cause you to seek that yourselves.

The study of the laws of physiology, practically applied, is the only means to the foundation and development of a solid personal morality. Let us then:

"Enter the path! There springs the healing stream. Quenching all thirst! There bloom immortal flowers carpeting life's way with joy; there throng swiftest and sweetest hours."

Then, and only then, the song of human misery will no more be; but in its stead ye shall read:

Lo! as the winds are, so is mortal life,
A moan, a sigh, a sob, a storm, a strife.

Hospital Notes.

UNIVERSITY HOSPITAL.

ACUTE RHEUMATISM RESULTING IN ANKYLOSIS.

PEPPER, at a recent clinic, presented a man aged twenty-nine years, who gave the following history: He had been in excellent health during childhood, but when he arrived at the age of puberty he contracted the habit of masturbation, which he practised to excess until the age of twenty. His constitution broke down under the excess, and he never recovered his previous good health. About four years ago he had an attack of acute articular rheumatism, which was followed by a number of attacks of a milder character. The left ankle-joint was most affected, and when the patient appeared before the clinic the articulation was completely ankylosed. There were no heart complications. Pepper mentioned that in his experience cases of articular rheumatism in which a number of joints were affected were much more liable to be followed by heart lesions than when only a single joint was involved.

As to treatment, he said he proposed to prescribe for the case as if it were one of chronic dyspepsia. He did not believe that the iodides or salicylates would be of the least service in improving the ankylosis, for which he indicated a local plan of treatment. Passive motion was to be applied twice a day, the patient not to be placed under the influence of an anæsthetic, as an acute inflammatory synovitis might easily be set up from excessive motion. The application of small blisters round the joint was also advocated, with attention to general hygiene, and avoidance of cold and damp.

COMPLETE PARAPLEGIA FROM CONCUSSION OF THE CERVICAL SPINE.

Ashhurst exhibited before his clinic a man aged twenty-four years, who a week previously, while intoxicated, fell off his car, the wheel passing over his neck. He was brought to the hospital in a comatose condition, but the symptoms were masked on account of the intoxicated condition of the patient. He had complete motor and sensory paralysis of both limbs, with priapism and involuntary discharge of urine and fæces. His temperature on admission was 97°, but rapidly rose to 100°, 101°, 102°, 103°. There was no paralytic affection of the upper extremities. An interesting feature of the case was the fact that although the weight of the car passing over his neck was very great, there was no injury to the larynx or the spinal column. Ashhurst said he considered the case one of concussion of the spine with some slight laceration of the cord, as the paralysis came on suddenly and rapidly improved. Since the patient was placed on treatment sensation completely returned in both legs, and motion was improved in the left leg, which showed that notwithstanding the severity of the injury the lesion was very light. He gave a very favorable prognosis. In discussing the clinical features of the case some interesting pathological facts were mentioned. When the patient was first seen his face was flushed and his pupils were contracted, due to irritation of the sympathetic, which also caused the elevation of temperature. The priapism, which was due to injury of the cervical portion of the cord, was very rare in dorsal or lumbar lesions. Ashhurst said it was formerly regarded as an absolutely fatal symptom, but now, while looked upon as very grave, it does not necessarily result in death.

Bed sores were caused either from constant pressure on prominent points or, what was more likely in cases of injury to the cord, to lesions of the trophic nerves which preside over the nutrition of the skin. The patient was at once placed on a water bed, the head being fixed by means of sand bags. Five-grain doses of iodide of potassium with twenty minims of fluid extract of ergot were ordered every four hours. When the acute symptoms subsided the patient would be placed on small doses of strychnia, with faradism to the muscles.

PHILADELPHIA HOSPITAL.

PARALYSIS AGITANS.

SINKLER showed a typical case of paralysis agitans, a man in whom the vacuous face, the Charcot hand, festination and muscular rigidity were all well marked. The man's position on standing was much stooped, and he walked with great difficulty on account of the constant rigidity of the muscles. Though Charcot says that there is never tremor of the head in paralysis agitans, Sinkler remarked that a case had been in the hospital some time since of undoubted tremor of the head. He attributes the rarity of this tremor partly to the fact that the muscles of the neck are nearly always in use holding the head in position, and in paralysis agitans tremor is slightly or not apparent when the muscle is in use.

The causes are many and sometimes obscure. Great shock is one. Under this head he related the

case of a business man who was standing by an elevator shaft, when suddenly the rope having parted the elevator dashed by him, having in it several workmen. The sudden shock gave rise to a tremor in the right hand; shortly afterward the left was affected, and in time the disease became general.

A woman was exhibited at the same time with this disease, the origin of which was traced to a fall from a chair while she was cleaning windows.

ARTHRITIS.

Ransley showed a case of beginning arthritis of the knee, rapidly improving under the simple treatment of absolute rest with extension and counter-extension. He dwelt on the importance of recognizing these cases early and beginning treatment, citing an instance of last week in which he had been compelled to resect the joint because the disease had progressed so far.

ABSCESSES IN DIARRHŒA.

A child, of about a year's age, has an ugly abscess in the left parietal bone. It has had diarrhœa for some time, and abscesses are likely to occur in such conditions. For diarrhœa with mucous and green stools, Ransley gives gr. $\frac{1}{80}$ mercuric chloride every three hours. In one day the mucus is generally absent from the stools and the green color gone.

If boils and abscesses have broken out he adds to each bottle of milk, preferably condensed, a teaspoonful of malt extract, and gives calcium sulphide gr. $\frac{1}{10}$, every two hours.

BUBO.

Ransley scraped out a suppurating bubo of the groin, and held that suppuration was seldom necessary in these enlargements.

His first treatment for buboes is to apply a preparation composed of collodion ℥ij, and iodoform ℥ij. If suppuration is threatened he gives calcium sulphide gr. $\frac{1}{10}$–$\frac{1}{8}$ every two or three hours. He also puts three or four sponges over the part, holds them securely in place by a tight bandage, then pours on water. Strong and even pressure is thus secured. He never uses poultices.

MEDICO-CHIRURGICAL COLLEGE.

SARCOMA.

GARRETSON removed a large sarcoma of the under lip, making a neat plastic by filling the gap with skin taken from under the chin.

AXILLARY GLANDS.

Seven enlarged glands were removed from the right axilla of a woman whose right breast had been excised about a year since for cancer.

EMPHYSEMA.

Waugh showed an interesting case of this disease. The patient, a man of fifty-five, had suffered from dyspnœa for twelve years, quite severely within the last year. At every inspiration it is noticed that the intercostal spaces are depressed and the abdomen drawn in. This is due to the fact that the diaphragm is depressed by the enlarged lungs, and the accessory muscles of respiration called into play. The liver is depressed about three inches by the lungs, and the heart pushed downward and to the left by the same organ, the usual area of absolute heart dulness being quite resonant. He will be given iodide of potash, which has been found of service, though used empirically.

HOW TO GIVE ETHER.

Pancoast holds that as men are made drunk sooner when standing or sitting, while taking alcohol, than when in a recumbent posture, in like manner it takes less ether to produce anæsthesia if the patient sits up.

HOW TO CUT FOR A NEEDLE.

"Never cut directly down on a pin or a needle you wish to extract, but make a curved incision in the line of the wrinkles, lift up the trap door, and pull out the offending body."—*Pancoast.*

MAMMARY FIBROMA.

A fibroma some three inches in diameter was removed from a woman's left breast by Pancoast. There was a history of mammitis in the first place, followed by this growth, the latter being just on the verge of suppuration.

London Letter.

THE CORD IN EPILEPSY.

MR. FRANCIS GOTCH, assistant to the Professor of Physiology (Burdon Sanderson) in Oxford University, and Prof. Victor Horsley, have communicated to the Royal Society the results of some experiments on the electro-motive changes in the spinal cord following excitation of the cortex cerebri. Excitation of the cortex, as is well known, is invariably followed, in the higher animals, by a definite and characteristic sequence of muscular movements. Observation of these movements, however, could not tell us whether their peculiar character was to be attributed to the cortex or to the bulbo-spinal centres. In this research the electrical phenomena of the conducting tracts in the spinal cord were tested; the experiments were made on etherized monkeys and cats. The spinal cord was exposed in the lower dorsal region as low as the upper end of the lumbar enlargement, and prevented from drying or cooling by bathing with warm saline solution; it was then ligatured and divided below the knot; the division of two or three roots then permitted the cord to be raised from the canal without any great interference with the blood supply; a non-polarizable electrode was then placed in contact with the cut end of the cord and the knotted ligature, another with the longitudinal surface, 2 cm. from the cut end. A very delicate capillary electrometer was then connected with these electrodes. It was found that the cut surface was always negative to the longitudinal surface. This had been previously observed by Du Bois Raymond.

When the area in the cerebral cortex in which the centres for the movements of the lower limbs are

localized was stimulated, the electrometer showed an excursion opposed in direction to that of the difference between the longitudinal surface and cut end of the cord. This excursion persisted as long as the excitation lasted, and ceased when this was left off. Then after an interval of from one to three seconds there ensued a rhythmical succession of excursions each opposed in direction to the resting difference, some apparently single and others multiple. These lasted from twenty to thirty seconds and suddenly ceased. From this it is seen that during a cortical epileptiform discharge the electro-motive changes in the spinal cord are exactly parallel as regards the character of their sequence to the convulsions of the muscles as recorded by the graphic method.

When, after the removal of the cortex the corona radiata was stimulated, the electrometer connected with the cord showed the prolonged effect during the excitation, but not the rhythmical movements after excitation. From these experiments the authors arrive at the important conclusion, which is entirely in accord with theory found on clinical observation, that, since by the method adopted the influence of the lumbar bulbo-spinal centres is excluded, the existence of the epileptic rhythm in the dorsal regions of the spinal cord points to its being almost entirely of cortical origin.

Precancerous Conditions of the Tongue.—An instructive discussion on conditions of the tongue precedent to cancer took place recently at the Harveian Society. It was raised by Mr. Butlin, who stated that in a series of cases of cancer of the tongue he had found that a precancerous condition had existed in 70 per cent. Warty growths were the most serious of these conditions, and were more common than was generally supposed. He thought that leucoma and superficial glossitis predisposed to cancer, but patients might have such conditions for many years, even to the end of life, without cancer developing. The wart on a leucomatous case never got well, and always became cancerous. He thought it dangerous to attempt to cut away the superficial layer of the tongue in leucoma. He was disposed, on the contrary, to recommend the removal of the whole of the diseased area, or, at least, the fore part of the organ in cases of leucoma and chronic superficial glossitis in which warty growths had formed. Where a chronic affection of the tongue was associated with chronic non-specific skin lesions he strongly advised the internal administration of arsenic. The only case of leucoma which he had ever seen absolutely recover was under this treatment. Several speakers pointed out the objection to too limited an operation. Mr. Jacobson, who advocated the removal of one-half of the tongue, observed that small operations gave rise to severe hemorrhage, which obscured the view of the operator, and led to diseased portions being left behind.

Mr. A. E. Barker condemned the removal of wedges of the tongue and of half the organ. He advocated free removal, and thought that special attention should be paid to the deep dissection by the side of the tongue, where the lymphatics ran. Epithelioma of the tongue had a great power of diffusing itself. He would watch leucoma carefully, and operate as soon as any decided induration was noticeable.

Excision of the Tongue.—Mr. Barwell has published his further experience of the operation for excision devised by him. The mouth being gagged open, the tongue drawn forward, and the head thrown back, an incision is made over the hyoid bone in the middle line; the mylo-hyoid is divided, and the genio-hyoid and genio-hyo-glossi separated. Silk ligatures are carried through this wound and brought out into the mouth behind the last molar, one on each side. The *écraseur* wire, which is made of a strand of park-fencing wire rope, is pulled through into the mouth by one ligature, hooked on to a loop left on the other ligature, and pulled back into the wound again. An eyeless Liston's needle is then passed into the hyoid wound and brought out far back in the middle of the tongue; the *écraseur* wire is hitched over this, and then tightened until it comes out of the hyoid wound, where upon the supra-hyoid wound the loop of another *écraseur* is pressed well down in the incision just made, and being set to work completes the separation of the tongue, which is taken out from between the teeth; the nerves which are left hanging frayed out in the mouth are now cut off short, and a drainage-tube put in the hyoid wound with a piece of absorbent cotton beneath the chin. The advantages claimed for the operation are that:

1. It is almost bloodless.

2. The sensory nerves are severed at their exit from the groove on the jaw, therefore the stump of the tongue is insensitive to pain.

3. The wound left is infundibular, the mouth of the funnel being, of course, at its lowest part, so that the cavity, completely drained, is very easily kept clean and pure; therefore, there is no danger of septic pneumonia.

4. The patient suffers less after the operation. The results so far as recoveries are concerned appear excellent.

Treatment of Strumous Glands.—The treatment of strumous glands, a subject of perennial interest to practitioners, has been discussed recently at the Edinburgh Medico-Chirurgical Society; the injection of perchloride of mercury solution was condemned on all hands, but there was some difference of opinion as to scraping. Cases occurred in which the operation was immediately followed by an outburst of general tuberculosis, owing to the bacillus being afforded access to the general bloodstream. Professor Chiene, who preferred excision, thought that if scraping was resorted to it ought to be followed by the application of a strong antiseptic. Professor John Duncan had got good results from rest to the parts, which he had obtained by making the patient wear a kind of cuirass with a collar.

Iodoform and Hydro-naphthol.—Speaking of iodoform, the antiseptic properties of which are, as is well known, of a very low order, Professor Chiene said that, though he had the greatest faith in iodoform as a dressing in strumous cases, he believed its beneficial action was due to its so altering the character of the tissues as to lead to the production of a granulating surface, whereby the secondary infection

was prevented. He thought hydro-naphthol a most promising substitute since it was a powerful parasiticide, and almost innocuous to the tissues.

Milk Diet in Tropical "White Flux."—There is a form of tropical diarrhœa characterized by soreness of the mouth and tongue from denudation of epithelium, degeneration of the intestinal mucous surfaces, and continued wasting; the stools contain little or no bilious coloring, are white, copious, frothy, and are largely composed of shreds of undigested food. There is no jaundice, and no evidence of liver disorder; all the organs shrink, the skin is inelastic and subcutaneous fat disappears. The disease is intractable to treatment by drugs and may not yield to change to a temperate climate. The only effectual treatment is, says Sir Joseph Fayrer, to put the patient on an absolute milk diet. Cows' milk, he said, which in rare cases may be diluted with a third or fourth of plain or alkaline water, should be the only food, and should be taken in small quantities (nothing else of any kind being given) of from four to six ounces every hour. When the patient is imbibing from two to three or four quarts of milk in the twenty-four hours he is obtaining enough nourishment to support life and enable him to recover. After a month or six weeks, when the glazed condition of the tongue has disappeared, the regimen may be cautiously relaxed. General experience seems to be that when this treatment can be enforced early enough, and the patient can remove to a temperate climate, recovery always follows.

Dr. F. R. Barker, Surgeon, Army Medical Staff, has described a curious epidemic of syphilis occurring among soldiers stationed at Portsea. The sores appeared at the site of tattoo marks recently made by a pedlar. This man was with some difficulty discovered, and it was found that the mucuous membrane of his mouth was covered with mucous tubercles. Eventually he admitted that he had used his saliva for moistening the wounds, and one of the soldiers said for rubbing up his colors also. Out of twenty-three men tattooed twelve certainly contracted the disease, and two others were believed to have contracted it, but could not be traced; four men had had the disease before and did not contract it again, and five, all of whom said that the pedlar had not put his needles in his mouth or used his saliva while tattooing them escaped. The period of incubation varied from thirteen to eighty-seven days.

The injurious effect on the health of the operatives of the process of sizing cotton goods has again begun to attract the attention of politicians; three official enquiries have already been held, the last in 1884, and the reports in every case concurred in recognizing the mischievous consequences of sizing to health. The practice was, it is said, introduced during the cotton famine produced by the civil war. Inferior short cotton is treated with China clay mixed with an adhesive flour or starch paste, and with the chlorides of zinc, magnesium, and calcium, and some sulphate of magnesium which are added mainly to prevent the mildew. In this way the customers are defrauded, and incidentally the health of the operatives is ruined, for the work has to be carried on in sheds carefully closed against ventilation and kept hot and moist by jets of steam. The operatives suffer from diaphoresis, prostration, vertigo, anorexia, and are very prone to rheumatism and to pneumonia, phthisis and other lung affections. Dr. Arlidge, in the third lecture of the course of four Milroy lectures before the Royal College of Physicians on Occupations and Travels in Relation to Public Health, has dealt with the subject briefly but clearly.

The date of the meeting of the British Medical Association in Leeds, this year, has been altered to suit local arrangements from July 30, 31, August 1 and 2, to August 13, 14, 15 and 16. The meeting is likely to be very successful unless the knot of metropolitan members who wish to alter the character of the journal, should raise a controversy and publicly secede; an intention with which they are credited in some quarters. Old members of the association treat this new agitation very lightly; the association they say has never been heartily accepted in London, and the more "influential" London members have already on two occasions seceded in a body, but have returned seriatim. The complaint now made against the management of the journal, which, in the estimation of the makers, appears to be most serious, is that some or many of the advertisements published are not consistent with the honor and dignity of the profession. That there is some truth in this cannot be denied, but the journal is far less open to the charge than almost any other medical periodical. The management has, as a matter of fact, refused a considerable number of advertisements which the other medical papers published in London insert without scruple; a good many more have to be modified by the advertisers before they are accepted for insertion. Whether anything of advantage to the profession at large will result from the agitation appears to me very doubtful. However this may be, the Leeds meeting ought to be very interesting.

The Royal College of Surgeons.—There is at present a state of armed neutrality observed between the members of the Royal College of Surgeons, and the Council of that body; but the conflict is likely to break out again as soon as the law courts have given decisions in the pending suits. Meanwhile the members are keeping careful watch on the council, and questions are frequently asked in Parliament, thereby giving the quarrel an amount of publicity little foreseen by the Council.

Dr. George Johnston, the well-known obstetric physician of Dublin, died recently, at the age of seventy-five. He was Master of the Rotunda Hospital from 1868 to 1875, and published the statistics of nearly fourteen thousand cases observed there.

Dr. J. A. Myrtle, of Harrogate, has recorded a case in which symptoms of poisoning followed the use of an eye lotion containing 1 per cent. of cocaine; not more than gr. $\frac{1}{11}$ could have been introduced into each eye, nevertheless the patient, a lady, aged forty-five, in a few minutes experienced numbness in the back of the tongue and throat, followed by intense palpitation, irregular action of the heart, disposition to faint, extreme nausea, and flatulent distension.

SALUTATORY.

IN presenting to our readers the initial number of THE TIMES AND REGISTER we are not launching a new journal. Each of the periodicals represented has already filled a place in the journalistic field, and approved by success its right to exist. Their union means increased efficiency and greater value, by concentrating in one the best elements of three. There are certainly more medical journals than are needed. Our tables are loaded with sample copies enough to bankrupt the physician who subscribes to all. Scarcely a month passes when we are not called upon to chronicle the advent of new candidates for favor, and if their demise is not often announced their disappearance from our exchange table tells the story. And yet we rarely examine one of these which has not some good features; some valid reason for being, though, perhaps, not for independent existence. With all due deference to the shades of Charles Darwin, it is not always and in every respect the fittest which survives. A special and inestimable suitability may be lost by reason of unfitness in other respects. A journal is brought into existence either to introduce a single idea, or a man, who believes he has that to say which it imports the world to hear. It may represent a specialty sufficiently important in its way but not of enough general interest to win a supporting patronage. There are few, if any, specialties which are not better represented by departments in a general journal than in a publication intended exclusively for a class too small to support it properly. Even the most exclusive laparotomist would be benefited by perusing a journal devoted to general medicine with a gynecic department.

The one-man journal is quite as objectionable as that built on one idea. No editor, however versatile, can help becoming tiresome to his readers when they have become familiar with his methods, and he has written out his opinions. The field of medical thought is too vast for one eye to pierce to its bounds in every direction.

For these reasons we believe that the model journal should have a large editorial corps, composed of men whose opinions are entitled to respect, embracing general and special practitioners in as great a variety of conditions as can be secured. They should be active practitioners, as journals edited by men who do not practise invariably show the lack of that keen discrimination which comes from actual experience. Such publications inevitably lose their fitness as helps to the worker, and degenerate into museums for the preservation of curiosities. This unfitness for every-day needs has been not inaptly expressed by designating this class as "kid-glove journals."

As a beginning towards supplying such a journal as we believe the profession needs, we have united the Philadelphia MEDICAL TIMES, THE MEDICAL REGISTER, and THE DIETETIC GAZETTE. The publication will be a weekly, with a quarterly number devoted solely to physiological medicine. We have secured the coöperation of a number of distinguished physicians, in this country and abroad, forming the American Medical Press Association. The list of members will be published as soon as it has been completed. The Journal is strictly independent, and not an organ of any society, college, city, or firm. Its columns are open for the discussion of any matters of interest to the profession. It is especially the practitioner whose wants we seek to supply; and to this class we look for support in material as well as subscriptions. The departments which have met with approval in the three journals will be continued, and such others added as future experience may render advisable.

Annotations.

THE SERVICES.

IT seems to become more difficult each successive year to secure suitable men for the medical corps of the Army and Navy. Many candidates present themselves, but fail to come up to the requisite standard, which is high, but not more so than the importance of the service demands. The difficulty seems to be in the rank. Physicians who have devoted themselves to the study of their profession until they are able to pass the entrance examination, are not the class of men who care to be put with a parcel of prankish midshipmen in the steerage. A studious man under such circumstances has little opportunity to continue his work, and is apt to become the target for all sorts of practical jokes, unless he gives up his studies and joins the rioters. Were it not for this, the position would be very desirable, as the pay is fairly good compared with what a physician can reasonably expect to gain from his first years of private practice; and the opportunity to travel in foreign lands, with the advantage of an official character, is not to be despised.

ART STUDIES IN MEDICINE.

THE time is coming when painters will not only have to study anatomy, but will have to take a course in medicine if they desire to be above adverse criticism.

In a monograph, *Les Demoniques dans l'Art*, by MM. Charcot and Richer, they show the similarity between modern attacks of hystero-epilepsy and ancient works of art, paintings, mosaics, and the like, illustrating the exorcism of evil spirits by various saints, from those possessed by the devil. Some of the positions depicted are remarkably correct, but of others the authors say that, if a patient assumed such an appearance before a physician at the present time, he would be accused of shamming, so that if the old masters had lived till to-day, some of them at least would be compelled to make some alterations.

For instance, Raphael in his great picture of the Transfiguration, depicts the attitude of the young man possessed of an evil spirit thus: One arm is thrown up and the other contracted in pronation with the fingers extended; the head is thrown back and the mouth is wide open, but at the same time the feet are planted firmly on the ground.

THE DISPENSARY NUISANCE.

THE *Provincial Medical Journal*, April 1, contains a strong editorial with regard to dispensaries in English cities, where this nuisance has proportions probably as large as and perhaps larger than here. There are so many hospitals ready to give, without price, medicine and advice from the most eminent medical men, that ordinary practitioners and especially young ones are driven to the wall. Many of them to eke out a living establish private shilling dispensaries, numbers of people being willing to pay that trifling sum rather than go to a somewhat public hospital.

A paper recently written shows that over two hundred thousand patients received free treatment at our Philadelphia hospitals and dispensaries during the year 1888. Doubtless three-fourths of this number could have afforded to pay more or less for treatment, but when they can go to a dispensary or hospital and be treated for nothing by the great Dr. Bismuth, will they voluntarily hand the humble practitioner next door fifty cents or a dollar? Most decidededly they will not, and our dispensaries are attended by a yearly increasing percentage of people fully able to pay, if dress is any criterion, but who consider it not in the least humiliating to sit for two or three hours in close companionship with smirched representatives from the slums, all alike waiting for the gratuitous treatment from beneficent Dr. Bismuth.

Nor does the two hundred thousand mentioned above include the multitude whose ailments are treated over the counter by the intelligent pharmacist.

In fact matters have almost come to such a state that only the "upper crust," the wealthy, and the higher middle class go to a physician's private office for advice, and then it is generally to an eminent man rather than to the one unknown to fame; so that the struggle for existence is becoming as severe in this country as it already is in England.

Why should skilled medical advice, the result of knowledge gained by years of hard study and the outlay of many hundreds of dollars, be given promiscuously, thrown broadcast to whomsoever chooses to take it? Why should the medical profession be held in a manner responsible for the thousand and one physical ills that assail humanity, frequently arising from wanton violation of the known laws of health?

In short, what is peculiar about a physician's knowledge that it should be free to all, deserving or undeserving, when people are ready and willing, and expect to pay their butcher, their baker, and their grocer for physical food; their dentist and their lawyer for counsel and treatment; and even their clergymen for spiritual subsistence and religious opinions?

It is time for the profession to wake up and put some restrictions on this free dispensary nuisance, else in time it seems as if it might assume such proportions that even the great Dr. Bismuth may find his twenty dollar patient of one day calmly seated on the next in the doctor's dispensary room, waiting with one hundred others for the great man's free prescriptions.

OBSCURE EPIDEMIC INFLUENCES.

WE cannot recall a time when there was such a tendency for colds to develop into pneumonia as at present. Catarrhs, however trifling, need to be watched just now.

We all know how certain affections tend to appear in groups. Perhaps a case of tonsillitis will not appear on our books for months, and then within two weeks we shall have a dozen cases. Or, an apparent epidemic of felons, boils, rheumatism, myalgia, heart affections, or duodenal catarrh, makes its appearance. Beggars, tramps, and the scamps who clear off our hat-racks and office tables also seem to recur in nebulous groups, with certain intermissions. The former visitations are usually set down to "epidemic general influences," "waves of influenza," etc., which simply recognizes the presence of a morbific influence without attempting to account for it, or explain its nature.

Whether the human inflictions are also governed by generally prevalent influences of an epidemic nature is a question to which attention has not yet been given. The learned author of the theory that inebriety is a contagious disease would probably hold that the periodic appearance of the sneak-thief is due to a microbic invasion. In support of this position he could point to the hitherto unexplained actions of the small boy; who, throughout this broad land, begins to fly kites, spin tops, shoot marbles, etc., when the proper time arrives, without previous understanding or concurrence.

It is not enough that the bacteriologist attributes the various physiological functions to his little protegés, but we shall have the processes and emotions of the mind explained in the same manner. Not only are digestion, assimilation, and oxygenation carried on by armies of microbes, but if in the spring the young man's fancy lightly turns to thoughts of love, it is simply because the vernal season furnishes conditions suitable for the activity of the amatory microbe, and in the youthful male organization it finds a suitable nidus for its development. What next?

Letters to the Editor.

ANOMALOUS CASES IN PRACTICE.

HYDROCEPHALUS.

WAS called to see Mrs. Mc., an Irish woman, nineteen years of age, primipara, who had been under the care of a midwife for thirty-six hours, with hard labor-pains during the greater portion of the last twenty-four, but on my arrival she said that the pains had been stopped for two or three hours. I noticed that her abdomen was unusually large for an ordinary case; no fœtal circulation could be obtained; the pelvis was well developed. On examination, per vaginam, I found the os uteri well dilated and soft, and pressing against it a large and slightly convex surface, which seemed to cover every part of the superior strait without engaging, and varying in consistence at different points; soft and fluctuating pieces of bone were very perceptible, with soft interspaces. I diagnosed a case of hydrocephalus. Placing the patient in a proper position, I perforated the cranium, two and a half gallons of serum escaping. As soon as the head began to collapse, the pains returned, and by passing a blunt hook into the opening in the skull, and making gentle traction during the pains, I had no difficulty in removing a male fœtus, which had the appearance of having been dead for several days. The recovery was tedious.

BILATERAL FRACTURE OF INFERIOR MAXILLA.

C. S., forty-seven years of age, was kicked on the lower jaw by a horse, cutting loose the entire lip, except a small portion at one angle of the mouth, knocking off almost the whole of the alveolar process, with thirteen teeth, as well as three out of the upper maxilla, and producing a compound comminuted fracture on each side about the middle of the horizontal ramus. There was considerable hemorrhage, which was easily controlled. After cleansing the parts thoroughly we removed a number of fragments of bone, some quite small, the largest being about an inch in length, and quite slender. A few of them came from the upper maxilla where the three teeth were knocked out, the fragments in all amounting to thirty or forty. When I first saw him he was comatose, from which condition he did not entirely recover for seventy-two hours.

Treament.—Used Hamilton's apparatus for fracture of the inferior maxilla, changing it slightly for the accommodation of the wound in the lip, which was held together by an interrupted suture. The local application was a weak solution of carbolic acid. The fractures united readily, leaving but slight deformity.

COMPOUND FRACTURE OF HUMERUS.

Was called to see a boy, twelve years of age, who had been thrown from a horse and received a compound fracture of the lower extremity of the humerus; found the fractured extremity of the upper fragment of the bone resting in the bend of the elbow. After thoroughly washing the parts, I put him under the influence of ether and reduced the fracture, also taking a couple of stitches; I then placed the arm in a Day's angular splint, passing a few broad strips of bandage around it, leaving the wound as easily of access for frequent dressing as possible, depending mostly on sol. bichloride of mercury. Anchylosis was threatened, but the boy now says that his elbow and his arm are as good as ever.

PERMANENT CURE OF HYDROCELE.

Was summoned to visit some cases at the County Infirmary. The first was a middle-aged German with hydrocele, whom I tapped, leaving him in charge of the steward, intending to return in a few minutes and remove the canula, but forgot it. The next day, on my return to the Infirmary, the steward asked me how long I was going to let that tube stay in that fellow's scrotum, as it was paining him very much; I told him that I thought it had been in long enough, and on examining him I found the serum thoroughly evacuated, his scrotum swollen and feverish. I withdrew the canula and gave him some general treatment, and a permanent cure was the result.

T. G. STEPHENS, M.D.

SIDNEY, IOWA.

TYPHOID FEVER.

NOTICING the earnest discussion upon this fever, and the various opinions expressed, I desire to say, through the columns of your Journal, that I recognize the fact that typhoid fever is caused by the introduction into the system of a living germ, and that this germ has its origin in decaying organic matter, both vegetable and animal, and that it is taken into the system in the water we drink, the food we eat, and, possibly, in the air we breathe; that its favorite lodging place is the glands of Peyer, the mesenteric glands, and the spleen; that its active working existence is two weeks, at the end of which time it reproduces itself and dies. This new production springs at once into an active existence, does its life work, reproduces itself, and at the end of the next two weeks has died. Thus they would go on indefinitely but for the production of a ptomaine, which becomes so acrid as to prevent their reproduction. This typhoid germ reproduces itself by the giving off of spores, or by budding, as the yeast plant is reproduced.

This ptomaine I believe to be an exhalation from their bodies, while living, from their excretions, and the decaying bodies of the dead. I do not believe the fever is the result of the inflammation of the glands of the bowels, or that of the spleen, but it is caused by this ptomaine, which has been carried by the blood to every part of the system, producing such a depression upon the nerve centres as to destroy the soundness and purity of their action.

The great question now is, can typhoid fever be cured? Having recognized the cause, I will say yes. I know that most of our authorities say it cannot; that we must be content with following it down the stream, and guarding as best we can against the breaking shoal.

There are but few kinds of fever that start like typhoid. In a few days we know if it is of the inter-

mitting type, and but little longer to know if remitting. If neither, I at once suspect typhoid, and begin my treatment accordingly. I would think it almost criminal to let my fever run two, three, or four weeks before deciding it a case of typhoid.

My average treatment is simply this : One-tenth of a grain of calomel, or its equivalent of the bichloride of mercury, every four hours, and a teaspoonful of an emulsion of spts. turpentine half way between. At bedtime I give a warm sponge bath, under the covers ; bathe the bowels freely with turpentine and put the patient to bed for the night, giving no more medicine until after the next breakfast. Give all the cold water the patient wants, and liquid, nourishing food. If the bowels do not move freely each day I move them with castor oil. When they move too freely I combine with my calomel Dover's powder ; opium, if necessary. This I continue every day until the fever is broken, which result I confidently expect from the tenth to the fourteenth day. When the fever is broken and patient perspiring freely, I change the treatment to tonics and mineral acids, and expect a speedy and complete recovery. With this treatment the fever will not run very high ; the patient does not become delirious. But if you change the treatment to tonics before the fever is broken the fever will run high, the patient grow weak and trembling, and you will have delirium.

I have not had to visit an uncomplicated case of typhoid fever longer than the fourteenth day since I have strictly adhered to this treatment, which is now nearly seven years. With this treatment what have I done ? First, with the calomel, I have aroused to their best action all the secretions of the alimentary canal ; I have the best possible action of the liver. In these small doses I also get a pleasant tonic action, and recognizing the fact of its changing to corrosive sublimate while in the stomach, I have one of the finest germicides, by which with the germicidal action of the turpentine, I prevent the reproduction of the typhoid germ, so that at the end of the first two weeks the old germs have died, and I have prevented their reproduction. The cause of the fever is gone, and the patient speedily returns to health. With the small repeated doses of turpentine I have also secured its stimulating action upon the nervous system. The attack is shortened and the danger of heart failure and of perforation of the bowels is lessened. Dr. Henry Hartshorne will say, "I tried that treatment more than twenty years ago and got beneficial results, but not such as these." So he did, but he orders this treatment during the first week, only leaving it off the second, and in that second week the germ is reproduced and the fever goes on. Dr. G. B. Wood will say, "I ordered this treatment farther on in the disease. I also got good results, but not such as these." So he did, but he does not order it until the most poisonous symptoms have manifested themselves ; not until this ptomaine has become so abundant and so acrid as already to have almost, if not quite, stopped the further reproduction of the germ ; but he now has a patient whose nervous centres have become so depressed with the load of poison that it may take weeks of careful treatment to free them and restore to health, during which time the ulceration of the glands of the bowels has been going on, largely increasing the danger from perforation, and the heart's action may fail through nervous exhaustion and spinal complications, or pneumonia may occur. I hope my professional brothers will carefully test this treatment and report results.

W. O'Neall Mendenhall, M.D.
Richmond, Ind.

MULTIPLE ARTICULAR ABSCESSES IN INFANTS—RECOVERY.

L. E., born of healthy parents, flourished until she was two weeks old, when intestinal trouble of an indefinite character set in, manifested chiefly by disorded appetite, and greenish, though not frequent stools. A week later an indurated, globular swelling, about one-half inch in diameter, was observed suddenly to make its appearance directly under the left nipple. Almost simultaneously a similar enlargement was discovered at the sacro-vertebral articulation. This latter was at first mistaken for a spina-bifida, which, on account of its small size, had been previously overlooked. Both swellings were exquisitely sensitive to touch, and shortly began to enlarge, until that on the thorax was the size of an English walnut, while the one on the back became half as large in its original location, but the entire right hip was subsequently involved in the swelling. Palpation at this time disclosed fluctuation of the thoracic tumor, which was then enveloped in a flax-seed meal poultice. Forty-eight hours afterward I lanced it, liberating a large quantity of creamy pus, which continued flowing for several days. The supposed spina-bifida now showed signs of suppuration, and was accordingly poulticed a sufficient time, when it was lanced with a result similar to that of the former. The swelling of the hip, however, still persisted, and eventually developed fluctuation, pointing about a half inch from the last incision. This was also poulticed and lanced. After it was thoroughly evacuated, the hip resumed its normal appearance and functions, which had been hitherto suspended. The child would now have been considered convalescent had it not been for the persistence of pyrexia. This had been present from the incipiency of the attack, and ranged from 101° to 103.5° F. ; indeed, it continued thus for several days after the evacuation of the last two abscesses which appeared respectively on the right wrist joint, and on the inner side of the left foot. These last abscesses repeated the history of the three former, in progress and treatment, with the exception that the right wrist remained indurated for several days after its abscess was lanced, and finally suppurated and pointed again, after which it yielded to inunctions of iodine ointment. The duration of the attack was three weeks, at the end of which time the child was apparently as well as any child of its age, not afflicted as it had been. It will be noticed that with one exception the abscesses were located over articulations, and, before suppurating, closely resembled the swelling of acute rheumatic arthritis. Treatment was accordingly directed to that condition

at first, and consisted of small doses of salicylate of soda, supplemented by one-twenty-fifth grain doses of morphia sulph as anodyne. The diagnosis of rheumatism failing to be substantiated by the progress of the case, the soda salt was supplanted by the compound syrup of trifolium as an alterative. The morphine was used throughout the attack, the child not being able to rest or sleep unless under its influence.

WM. S. CARY, M.D.

GOTHENBURG, NEB.

DIVISION OF TENDO-ACHILLIS.

H. C., a strong, healthy young man, about eighteen years of age, stepped backward and struck his heel against the edge of a recently ground scythe, severing with a clean cut the "tendo-Achillis" about one inch above the astragalus. The upper portion of the tendon retracted in its sheath nearly four inches.

Only a few drops of blood were lost. To meet the indications in this rare injury, I put on his foot a common slipper, after making a hole in the heel, through which I passed a piece of strong tape, and then tied the ends of the tape to a strap or bandage fixed above the knee, flexing the leg upon the thigh as far as possible. He remained in this position some four or five weeks. This was all the treatment, and the result was a perfect cure. My excuse for putting this case on record is that I have seen recently in a medical journal rather elaborate diagrams demonstrating in what manner the upper portion of the severed tendon could be brought down, and united with the lower, making a formidable operation for a young practitioner to accomplish.

GEORGE DAVENPORT, M.D.

NOTES FROM PRACTICE.

WHOOPING-COUGH.

WHOOPING-COUGH has been quite prevalent here for the past three months, but it has been of a mild character as a rule. Some very severe cases, however, have occurred in families in which other members have hardly whooped at all. Two cases of the former class, patients of my own, after having coughed three weeks without lessening very much, came to an abrupt stop in one day, having hardly anything of it after.

They had both been taking ammonia bromide with ipecac and hyoscyamus for two weeks, which have rather been my favorite remedies this year. Very young children will take the bromide nicely if mixed with simple syrup.

The too free use of nauseants is apt to lower the tone and force of the system, and interrupt the appetite and digestion. I have found hive syrup quite extensively used by common people, especially the Germans; but I always forbade its use in the cases of young children on account of its depressing effects. Older and stronger subjects bear it very well, and are often benefited by its use. The objection to very young children taking it is, of course, on account of the antimony contained in the preparation. I have found that the simple wearing a belladonna plaster upon the chest has a modifying effect upon the cough. The elixir val. ammonia I have found useful in several cases; its stimulating and antispasmodic properties being often indicated. Chloral at night is safe and useful, bringing about refreshing sleep better than any remedy that I have ever tried.

CASE OF CONVULSIONS.

At about 11 P.M. I was called to see a girl twelve years of age, who had had several hard convulsions. She had attended school the day before as usual, and was as well as she had ever been; had no particular mental strain or excitement. Her evening meal was well relished, but consisted of nothing extraordinary in quality or quantity. She retired at 9 o'clock, and at 10 o'clock, without the least warning, went into a terrible convulsion.

She was in the third when I arrived, and had remained totally unconscious from the first. I succeeded after a while in getting her to swallow fifteen grains of ipecacuanha, with a view to clear the stomach of ingesta. In about fifteen minutes this was done most thoroughly, but she immediately passed into another convulsion, and as soon as it had ceased I gave a copious injection of warm water, to which was added a spoonful of common salt. Her bowls moved quickly and freely, but the spasms still continued to occur with no abatement in force or frequency. The warm bath had not been neglected, but used to the full extent of safety. I now put her under the influence of chloroform by inhalation, which I continued for two hours. Several times on my stopping the anæsthetic, the spasm would begin, but would cease immediately on again applying the remedy. After two hours there was not a return, and the following day, though weak and sore, no other bad effect from the many convulsions was apparent.

EMBOLUS OF POPLITEAL ARTERY.

A young man, nineteen years of age, for four weeks had been the subject of acute rheumatism, with extensive heart complications. Early in January he was taken very suddenly with agonizing pain in the left leg, extending down to the foot, after having made an effort to get up so that his bed could be made. It was four hours from the beginning of the attack before I saw him. He was then suffering terribly, with the leg perfectly blanched, and cold as a cadaver.

A hypodermic of morphia and atropia was administered, which had the effect of somewhat relieving the pain, and artificial heat was vigorously and continuously applied.

It was a hard fight for the life of the limb for several weeks, when a compromise was effected by parting with the toes, but retaining the remainder of the leg.

The toes were removed, when a perfect line of demarcation was formed. The temperature of the leg is now the same as that of the sound one.

A loud, bellows murmur is heard at the heart, and twinges of rheumatism pretty distinctly felt, more or less general, over the body at every little change of

the atmosphere, although the affected limb seems to trouble him less than the other.

BLEEDING IN APOPLEXY.

Mr. S., while rising from his bed in the morning, suddenly became unconscious, and paralyzed in one-half of his body.

He was under the care of a homœopath for three days, with no apparent change occurring, when I was sent for. I found the patient with a pulse of 60, full and strong, face purple, and breathing stertorous; perfectly unconscious, with scarcely any power to swallow. I at once corded the arm and opened a vein. When a pint of blood had been extracted his consciousness returned, and he recognized and called me by name, though in a muffled sort of way.

He continued to improve after the venesection, and can now get about with the aid of a cane.

Mr. H., aged sixty, two weeks ago, while going from his house to the barn in the evening, became paralyzed and unconscious, falling to the ground. A physician was called, but did little for him. The next day I was called in consultation. The patient was comatose, pulse 60, face purple, totally unconscious.

He was bled copiously, when almost immediately his consciousness returned. Ten grains of calomel, with the same amount of rhubarb, operated freely in six hours, and the following day his mind was clear, and he could talk, but with some hesitation. In a few days he gradually relapsed into coma, and died.

Both of these individuals were excessive users of tobacco.

CANCER OF THE TONGUE.

Three cases of cancer of the tongue and throat have come under my care within two years here, and all of them occurred in inveterate smokers and chewers, and I think I may here state that I have never known cancer of the tongue to appear in an individual who was not a smoker, and a chewer of tobacco.

JOHN E. MEACHAN, M.D.

RACINE, WIS.

A CORRESPONDENT asks if in the event of his visiting Paris during the Exhibition, he will be permitted to practise among his own countrymen.

We have made inquiries and find that no such privilege will be granted. In case he could find a physician who is duly authorized, he might be allowed to practise under his cover.

Book Reviews.

ELECTRICITY IN THE DISEASES OF WOMEN, WITH SPECIAL REFERENCE TO THE APPLICATION OF STRONG CURRENTS. By G. BETTON MASSEY, M.D. Cloth. Illustrated. Pp. 210. Price, $1.50. Philadelphia: F. A. Davis, 1889.

A portion of the introductory chapters of the present work having been recently published in the *Times* as a series of contributed articles, the profession has already learned something of the author's aim and intention in bringing before the public the first attempt at a complete treatise on this subject.

The book is thoroughly practical, the object being not only to familiarize the profession with the physical properties of this great therapeutic agent, but to illustrate the advantages of its scientific application in the treatment of diseases of women. Whilst the material of which the author has made use is largely drawn from his own experience, which is frequently not the case in modern book construction, yet the opinions of such authorities as Apostoli, Engelmann, etc., have been rightly accorded some space. There are some exaggerations of statement to be found, which will doubtless be toned down by mature experience; but the reader who practises this special art will easily separate these from the balance of the book. It is a useful and well-timed treatise. Typographically, the book is all that could be desired, and reflects credit to publisher as well as author.

LES MALADES QUI GUÉRISSENT AUX EAUX D AIX-LES-BAINS, ET COMMENT ILS GUÉRISSENT. Par le DR. J. MONARD. Paris: A. Maloine, Éditeur, 91 Boul. St. Germain, 1889.

The author gives us a little book of 87 pages, with full information concerning this celebrated health resort. The first chapter treats of the general effects of the waters; the second takes up their use in surgical affections and skin diseases; the following, of syphilis and tuberculosis, general disorders of nutrition, hygiene of the bather, and the model thermal station, in which favorable mention is made of the city of Pullman.

The St. Louis Polyclinic, edited by L. A. Turnbull, M.D., appears as the organ of the St. Louis Post-Graduate School of Medicine. It is a monthly of 28 pages, at $1 per year, and all physicians who are specially interested in the above-named school should subscril e for it.

ANNALES DE LA POLYCL NIQUE DE BORDEAUX. A semi-monthly of 64 pages, appearing in January and July, and filled with reports from the clinics of the editors, MM. Moure, Pousson, and Dubreuilh.

Pamphlets.

Temperature and Atmospheric Humidity, and their Relations to Health and Disease. By J. M. Anders, M.D., Philadelphia.

The Control and Care of Pauper Inebriates of Towns and Cities. By L. D. Mason, M.D., Fort Hamilton, N. Y.

The Question of Relationship Between Lichen Planus and Lichen Ruber. By A. R. Robinson and S. Edin, New York.

Transactions of the Louisiana State Medical Society, New Orleans, 1888.

Apparatus for Pneumatic Treatment in Hospitals. By S. Solis Cohen, M.D., Philadelphia.

Surgical Treatment of Membranous Opacities in the Vitreous. By C. S. Bull, M.D., New York.

Relation of the Nasal and Neurotic Factors in the Ætiology of Asthma. By F. H. Bosworth, E. L. Shurly, W. H. Daly, and A. H. Smith, New York.

The Relation between Trophic Lesions and Diseases of the Nervous System. By E. C. Seguin, M.D., New York.

Laparotomy for Ascites. By T. A. Ashby, M.D., Baltimore.

The Importance of Careful Diagnosis of Pregnancy. By W. S. Stewart, A.M., M.D., Philadelphia.

Prevention and Treatment of Typhoid Fever. By S. S. Vurt, M.D., New York.

A Case of Double Vascular Exophthalmus. By C. J. Kepp, M.D., Newark, N. J.

Twelfth Annual Report of the Board of Health of the State of New Jersey, and Report of the Bureau of Vital Statistics, 1888.

Report of the Board of Health of the city of Reading, 1888.

Proceedings of the Department of Superintendence of the National Educational Association, Washington, 1888.

Contribution to the Diagnosis and Surgical Treatment of Tumors of the Cerebrum. By R. S. Weir, M.D., and E. C. Seguin, M.D., New York.

Common Membranous Sore Throat. By J. Solis Cohen, M.D., Philadelphia.

Biniodide of Mercury; Its Antiseptic Use. By E. P. Bernardy, M.D., Philadelphia.

Address of Albert R. Baker, M.D., at Wooster University, Cleveland, O.

Some Results of Excessive Conservatism in the Treatment of Disease in Large Joints. By Addinell Hewson, M.D., Philadelphia.

On the Treatment by Suspension of Locomotor Ataxia and some other Spinal Affections, as described by Prof. Charcot. Translated from the French and edited by A. de Watteville, London, 1889. Price, one shilling.

The Science of Successful Surgery. By John B. Roberts, M.D., Philadelphia.

Fixed Uteri. Uterine Hemorrhage. By Wm. L. Taylor, M.D., Philadelphia.

Lactopeptine Medical Annual. New York Pharmacal Association.

Preliminary Report to the Illinois State Board of Health.

Water Supplies of Illinois and the Pollution of its Streams. By John H. Rauch, M.D., Secretary.

VARIOLA AND COCAINE.—Dr. Cerni calls attention to the recent observations regarding the treatment of variola by the employment of cocaine in doses of from two to five centigrammes. The period of suppuration is said to be shortened to a remarkable extent.—*La Normandie Medicale.*

EMPLOYMENT OF TAR WITH IODOFORM.—M. Ehrman finds that this combination is, if anything, more efficacious than iodoform alone, besides which it possesses the advantages of absence of odor as well as cutaneous irritation.—*Revue de Therapeutique.*

Abstracts.

HYSTERIA AND PREGNANCY.—Dr. Brennan reports a case of neurasthenia that had proved intractable to all treatment, which was finally cured by becoming pregnant.—*La Normandie Medicale.*

OCCIPUT POSTERIOR.—T. Griswold Comstock, A. M., M.D., Ph.D. (*Clinical Reporter*), reports two cases of *labor with the occiput situated posteriorly* in which he was called in consultation, and in both of which he was compelled after vain efforts at forceps delivery to make use of craniotomy.

PLACENTA PRÆVIA.—The *Lancet* reports the occurrence of placenta prævia in five successive pregnancies, the writer tracing the predisposing cause to an abnormally large uterus.

TRYPSIN IN DIPHTHERIA OF INFANTS.—The following has been recommended as a membrane-solvent mixture:

℞.—Sodii bicarbonatis,
Trypsin . . . . . āā gr. xxx.
Hydrargyri chlor. cor. . . . . gr. ¼
Glycerini . . . . . ʒ j.
Aquæ rosæ . . . . . ʒ j.
Sig.—Use as a spray.

—*Merck's Bulletin.*

CORYZA.—J. G. Carpenter, M.D., (*Journal Am. Med. Assoc.*) contributes an interesting article on this common and troublesome complaint. Bromide of potash in first and second stages for the reflex and cutaneous irritability; iodide of potash acts specifically on the mucous membrane; grs. ii to x, along with grs. xxv bromide of potash, will often abort or cut short an attack. The hot foot bath for fifteen to thirty minutes, with water from 95° to 100° is good. In mild attacks of catarrh anointing the skin with vaseline and the free use of massage once or twice a day for one or more days, will abort an attack and assist the other medicines in accomplishing the same result.

Opium and its preparations are valuable; grains ¼, ½, or 1, repeated every two, three, or four hours, *pro re nata.*

RESPIRATION BY THE NOSE AND BY THE MOUTH.—The *Journal de Med. et. de Chi. Pratiq.*, 1888, No. 12, presents the following conclusions from a work published by Dr. Smelster. Inspiration is made by the nose or by the mouth. Simultaneous inspiration by the nose and by the mouth is physiologically and anatomically impossible. Expiration is made by the nose alone or by the mouth alone. Simultaneous expiration by the nose and by the mouth is physiologically and anatomically impossible. Therefore, respiration is never performed by two orifices at the same time.

A practical conclusion to be drawn from these facts is that an operation may be performed on one of these parts while inspiration is carried on by the other.—*Revue Médicale de Louvain.*

NITRITE OF AMYL or "glonoin" will often abort a cold in its incipiency.

A powder composed of quinine sulph., grs. ij; bismuth subnit., grs. ij; morphine sulph., gr. 1/8; cocaine muriat., gr. 1/8 to 1/4, well triturated and blown into each nostril two or three times in twenty-four hours, will abort or arrest cold in the first and second stages and shorten the duration in the third stage. As local applications these are good:

Spray affected parts with 2, 4, or 6 per cent. solution of muriate of cocaine in melted vaseline every eight hours; or

℞.—Vaselini . . . . . ℥ j.
Olei eucalypti . . . . . gtt. iij.
Acidi carbolici . . . . . gr. ss–iij.
M.—Ft. Massa.
Sig.—Melt and spray ℥i, ℥ij.

Or,

℞.—Vaselini . . . . . ℥ij.
Glycerini . . . . . ℥ss.
Acidi carbolici . . . . . gr. ss–ij.
M.—Ft. Massa.
Sig.—Melt and spray, ℥ss, ℥ij.

MASSAGE.—There are four terms expressive of the various manipulations in massage: 1. Effleurage, 2. Pétrissage, 3. Tapotement, 4. Friction.

1. *Effleurage.*—Stroking with the palm of hand, the tips of fingers, the thumb, the knuckles, or the edge of the hand. Effleurage has a soothing effect and relieves pain from tension, neuralgia, etc.

2. *Pétrissage* consists of pinching, pressing, squeezing, rolling and kneading. To be done centripetally, from periphery to trunk, in direction of the current of the lymphatic or venous vessels. This excites action upon the lymphatics and capillaries, stimulates circulation, promotes absorption, and improves nutrition.

3. *Tapotement.*—Tapping, percussing, tickling, hacking, thrusting, used for deeper muscles of the loins and back.

4. *Friction.*—Rubbing for superficial purposes.

To be more explicit: pressing is done with the thumb; tapping, the tips of the fingers slightly bent (useful in neuralgia of face and cranium); thrusting, using the finger-tips with extended hand; hacking, done with edge of hand, fingers kept apart or together; pinching, keeping thumb on one side and the four fingers on the opposite side, like a pair of pliers; squeezing, same as pinching, but the thumb alone coming into play, the fingers remaining passive; rolling and kneading, using both hands, thumb of both hands on one side, and the four fingers of the two hands on opposite side and manipulating like making dough. In addition to these movements of the limbs, at first passive, then active, are effected, consisting of flexion, extension, pronation, supination, rotation. These movements must be performed at first gently, and by degrees more energetically. The patient at first remains passive, the operator performs the movements for him; in active exercise, the patient performs these movements whilst the operator offers the resistance. The best costume for the patient is a suit of flannel.

Diseases in which massage is of undoubted benefit: Rheumatism, and in neuralgia when not due to inflammatory action; manner, stroking, kneading, hacking; obesity, arthritic joint affections, gentle manipulation continued over some months; paresis not due to organic disease, gentle treatment; narcotic poisoning, beating, pinching, hacking muscles over whole body; abdominal and pelvic swellings, pelvic inflammation and ovaritis, ovarian cysts in which operation is impracticable, eye diseases, conjunctivitis pustulosa, episcleritis, corneal opacities following pannus, and scrofulous and parenchymatous keratitis, eczema, centripetal stroking.—*Provinc. Med. Journal.*

A HINT FOR FACILITATING THE MICROSCOPICAL EXAMINATION OF URINE.—When attempting to examine urine under the microscope for casts, epithelial cells, and other organic bodies, a good deal of annoyance and difficulty is sometimes caused both by urates and also, when the specimen is not quite fresh, by fermentation and putrefactive products. In order to obviate this difficulty, and with the further view of preserving the specimen, Dr. M. Wendringer advises that the urine should be mixed with a nearly saturated solution of borax and boracic acid. This dissolves the urates and keeps the urine from fermenting, and at the same time exercises no destructive effect upon the casts and epithelial elements which it is desired to examine. The solution is prepared by mixing twelve parts of powdered borax in one hundred parts of hot water, and then adding a similar quantity of boracic acid, stirring the mixture well. It is filtered while hot. On long standing a small deposit crystallizes out, but clings to the side of the vessel, so that it does not interfere with the transparency of the liquid. The urine to be examined is put into a conical glass, and from a fifth to a third of its bulk of the boracic solution added to it and agitated with it. The urine will be found to become clear in a short time—i. e., if there is no cloudiness due to bacteria; and it will remain unchanged for several days. If it is only wanted to clear the urine and to make it keep for a day or two, the addition of a smaller quantity of the boracic solution is sufficient. If a third of its bulk is added, no fermentation or putrefactive processes take place, even if the glass is left uncovered in warm places. Albumen, too, if it exist, is not coagulated. The organic elements—as epithelial cells, casts, blood corpuscles, etc.—collect so quickly, without undergoing any morphological change at the bottom of the glass, that the first drop taken up by the pipette usually proves a satisfactory specimen.—*Lancet.*

TREATMENT OF TETANUS BY ABSOLUTE REST.—Prof. E. de Rienzi recommends absolute rest for the treatment of tetanus. Since the year 1882, when he applied the treatment for the first time, he has treated six cases of tetanus with the result of obtaining five cures. The following is a brief resume of the indications which the author gives for the treatment:

1. The patient having the ears stuffed with cotton or wax is to be kept in a quiet room and in total darkness.

2. The sick room, as well as the adjoining ones is to be thickly carpeted in order to avoid the noise of footsteps.

3d. The room is to be opened for ventilation every four hours with the greatest care. The diet is to consist of liquids, milk, eggs beaten in broth, water and wine, etc.

4. All light necessary shall carefully be covered from the sight of the sick.

5. If constipation exists, both purgatives and injection are interdicted. Above all quietness is necessary.

6. Should the pains be intense, with the object of quieting, powdered belladonna and ergot of rye should be used.—*Bulletin Gen. de Therapeutique.*

Nature and Treatment of Diphtheria.—Dr. P. Morot, of Vichy, regards diphtheria and croup as one of the manifestations of a uric acid diathesis which, under the form of a congestion of the pharynx or larynx causes the production of a false membrane. In all manifestations of this diathesis, but more especially in the two above-mentioned diseases, the liver is found to be in a state of congestion, and the congestion is the main indication for treatment.

The hot treatment for diphtheria therefore begins with the reduction of the hepatic congestion. This is easily effected by means of cauterization over the region of the liver, with acid nitric mono-hydrate by means of a pointed stick, taking care to remove all excess of acid.

This little operation is to be frequently renewed on the remaining healthy tissue every hour or two if necessary, until the liver returns to its original size.

With this effected we are told that he has seen an amelioration of all the symptoms of the disease, and as the author points out the same rule would hold good as a preventive during the prevalence of an epidemic. Quinine and strychnia are considered the most useful drugs.—*Revue de Therapeutique.*

Toxic Effects of Cocaine.—In *Brit. Med. Jour.*, April 6, is reported a case of marked poisonous effects from the instillation into each eye night and morning, of three drops of a three per cent. solution of hydrochlorate of cocaine.

Immediately after the drops were applied "she felt a peculiar sense of numbness in the back of the tongue and throat, followed by intense palpitation, irregular action of the heart, disposition to faint, and extreme nausea, amounting almost to vomiting; she also had to unfasten her clothes owing to the sudden and great distension of the stomach and bowels with flatulence. The symptoms lasted for hours after each application of the drops. She was seen the third day after this treatment was commenced, and, the evil effects of the cocaine being recognized, the drops were discontinued, with the result that the disturbing cardiac and abdominal symptoms disappeared."

The Potato Cure.—Prof. Billroth, at his clinic, presented several cases of foreign body in the intestines. The patient was recommended to eat large quantities of potatoes, which produce a uniform distension of the intestinal tube and thus cause the expulsion of the foreign substance. He claims that the necessity for gastrotomy was thus avoided.—*Revue de Therapeutique.*

Our readers may have noticed the ingenious little instrument which has been found to be so useful in cleaning glass windows. It consists of a band of flexible rubber held between two strips of wood. We learn from the *Journal of Hygiene* that a modification of the same is used by the street cleaning bureau of Paris on the asphalt streets of that city with very satisfactory results.

Erysipelas.—Dr. Behrend treated erysipelas in the first stages with a lotion of absolute alcohol, ninety per cent., three times a day, with very good results. All the pain disappeared, so did the redness and swelling, and no case ever went on to suppuration, though he had many cases in his capacity as physician to the prison for women in Sagua. The patients under this treatment were able to work, and complete cure was obtained in all cases in from three to five days.—*Berliner Klinische Wochenschrift.*

Treatment of Stricture of the Œsophagus by Electrolysis. — The case reported by Dr. Dujardin-Beaumetz was operated upon by Dr. Fort in the same manner as for urethral stricture. The stricture which measured but five millimetres in diameter now measures fourteen, and the patient who was dying from inanition, being hardly able to take a few drops of broth, now eats everything, and has gained nine pounds in weight. This is supposed to be the first operation of its kind, and the success is complete.—*Bulletin de l'Academie de Médecine.*

Syphilis.—In fifty cases of syphilis of long standing, and where the mercury treatment even had failed, Dr. S. E. Gentz had excellent results by the hypodermic injection of one-sixth of a grain of bicyanide of mercury every day until all symptoms of the disease disappeared. The solution has to be made fresh every other day, and must be well closed in the bottle to shut off the air. If this is not done, hydrocyanic acid will be evolved and mercury be precipitated.—*Wein. Med. Presse.*

Cocaine in Smallpox.—Dr. E. Ory used a solution of hydrochlorate of cocaine, five per cent., in variola and varioloid with very good results. He gives ten drops four times a day to an adult patient of the above solution with very good results. Five days after the eruption appeared the patient was cured in several cases without leaving any pitting whatever. To children he gives eight drops four times a day of a one per cent. solution with the same good results. He thinks it also would act happily as a prophylactic.

PHARMACOLOGY AND THERAPEUTICS.—We quote the following interesting notes on pharmacology and therapeutics from the London *Lancet* of April 6:

"*Simple Method of Treating Coryza.*—Camphor in various forms is frequently recommended for colds in the head, although Dr. George Johnson and others long since indicated the dangers attending the use of concentrated alcoholic solutions. The following method of application is suggested in a Swiss pharmaceutical journal, and certainly has the merit of simplicity:—A jug is half-filled with boiling water, into which a teaspoonful of well-powdered camphor is thrown. A funnel-shaped paper cap is then placed on top of the jug, and a hole torn in it just fitting the nose. The camphorated steam is inhaled through the nose for ten or fifteen minutes, the inhalation being repeated if required every four or five hours. If the patient resolutely persists with the inhalation, in spite of its unpleasantness, it is said that three repetitions will always effect a cure, however severe the coryza may be.

"*Carbolic Acid and Iodine in Whooping-Cough.*—Dr. Rothe, having met with some unfortunate cases of whooping-cough treated with antipyrin, turned his attention to a combination of iodine with carbolic acid in the treatment of this affection, and with this combination he has obtained remarkable results. He has, he says, treated hundreds of cases, and cannot remember one in which the affection lasted longer than four weeks, besides which no fatal case occurred. The mixture he employs is as follows: acid. carbol., 14 gr.; sp. vin., 15 gr.; tinct. iod., 10 gtt.; tinct. bellad., 30 gr.; aq. menth. pip., 2 oz.; syr. opiat., 150 gr. A teaspoonful of this is given to children over two years of age every two hours. When this treatment was carried out from the commencement of the complaint the severity was never great, and even when it was only begun in cases that had been going on for six or seven weeks it soon cut them short.

"*Iodine Applications in Erysipelas.*—Dr. Tichomirow, writing in a Russian military medical journal, recommends the employment of tincture of iodine as an external application in erysipelas even in cases where bullæ have formed. He paints the iodine over the affected part and its vicinity three or four times a day. The irritation caused by the treatment is easily allayed by the application of a little camphorated oil. Usually he found a couple of days sufficient to reduce the infiltration and to bring the temperature down to normal. A similar mode of treatment he also considers very beneficial in cases of boils and carbuncles. Even after these have broken he recommends that the iodine should still be applied, the wound being cleansed from pus and a dressing of cotton-wool applied.

"*Phenacetine in Whooping-Cough.*—Dr. Heimann, of Landau, writing in the *Münchener Med. Wochenschrift*, states that he was induced to try the effect of phenacetine in whooping-cough as he had been very much disappointed with antipyrin. Although he has given children of three or four years old a few doses of fifteen grains each of phenacetine, he has never found any ill-effects from its use, and the results, he says, have been uniformly satisfactory.

"*Creoline in Suppurative Otitis.*—The use of creoline in ear diseases is strongly recommended by Dr. Purjesz of Buda-Pesth. In cases of acute and chronic inflammation of the middle ear he syringes once or twice daily with a solution containing five or six drops of creoline to about nine ounces of water, in addition to which the Eustachian tube is opened up by the employment of Politzer's method, or, if necessary, by means of catheterisation. Dr. Purjesz finds that creoline is an excellent antiseptic for this purpose, and in the strength employed by him quite free from any objection on the score of causing irritation. Its low price, too, makes it especially suitable in practice amongst the poor.

"*Picric Acid Applications in Erysipelas.*—A solution of picric acid in water, of the strength of 6 to 1000, is strongly recommended by Dr. Cavelli as an external application in erysipelas, whether of a slight or of a severe character. In cases where the prostration has been considerable, together with delirium and a high temperature, painting the affected part with the solution from five to ten times a day very soon brought down the swelling in the cellular tissue and reduced the fever. The same treatment is also recommended in cases of lymphangitis and eczema.

"*Creasote in Diabetes.*—Two cases of diabetes have been treated with excellent results by Valentini, by means of creasote administered internally. In one case, four drops per diem were given at first, this quantity being afterwards increased to ten drops. Under this treatment the sugar disappeared, and did not return when the patient began to eat starchy food. The other patient was given six drops per diem, and did equally well."

THE CURE OF BUNIONS BY PHENIC ACID.—Dr. Salemi, of Nice, uses the following method: The foot is washed with soap and water, after which the adjoining healthy parts are protected by a thick coat of elastic collodion. The acid is now melted and applied to the hardened surface by means of a pointed brush. After allowing it to dry for several minutes the excess of acid remaining may be taken up with ordinary blotting paper. This application should be repeated every three or four days until a cure results.—*Revue Médicale de Louvain.*

RECENT STATISTICS OF RABIES.—In a communication to the Academy of Medicine, M. Dujardin-Beaumetz gives the following data concerning râbies in the Department of the Seine: Of those who followed the complete Pasteurian treatment, 105 persons were wounded by animals whose râbies was proved by experiment; 231 by animals which were pronounced rabid by veterinarians; and 49 by animals of unknown character. Leaving out the last named, the mortality was 1.19 per cent. One hundred and five did not follow the Pasteurian method of treatment, and of these 14 died, a mortality of 13.33 per cent.

Medical News and Miscellany.

Dr. C. F. Hertzog has located at Oley, Berks County, Pa.

"It" has been definitely decided to be ordinary spring fever.

Iodol is recommended internally and locally in tertiary syphilis.

The Society of American Anatomists meets in Philadelphia this fall.

We were favored with a call from Dr. Emil Kleen, the Swedish physician of Carlsbad.

The Yellow Fever Epidemic of 1878 cost this country 25,000 lives and $200,000,000.—*Sanitary Inspector.*

Denver, Colorado, has only three medical colleges. The combined graduating classes this year numbered nineteen.

At Singapore, dogs are subjected to fifteen days quarantine; the owners being compelled to pay fifteen cents per day.

Dr. Steer has been confined to his residence with a very severe attack of diphtheria, contracted while attending a patient.

Dr. Leuf, of the University of Pennsylvania, may be considered a specialist upon the affections peculiar to base-ball players.

Ether drinking is becoming prevalent in the north of Ireland. It takes a pretty strong stimulant to fuddle the brain of a Far-Down.

In the *Boston M. and S. Journal* Dr. Wadsworth reports the removal of a bit of steel from the vitreous humor by means of an electro-magnet.

A New fashion has appeared in the drapery of doors where a death has occurred. Instead of the heavy streamers of crape, pendants of natural flowers are used.

Dr. H. A. Starkey will probably locate at that delightful suburb, Lansdowne, which, by the way, is being built up with a rapidity only excelled by Aladdin's genii.

Dr. W. X. Sudduth is making a great success with the *International Dental Journal*, which has already won a high place in the estimation of the dental profession.

Pilocarpine has been employed with success by veterinarians in the treatment of acute laminitis. The dose varied from six to twelve grains, given hypodermically.—*Amer. Vet. Review.*

It looks as if the long-felt want of a remedy for influenza had been found in the febricide pills. We have given one every four hours, in a number of cases, with very promising results.

Medical Statistics. — According to a recent census the proportion of physicians to each 100,000 inhabitants is as follows: United States, 122; Germany, 70; England, 66; Belgium, 54; France, 29.

Mlle. Guiseppina Cattani has made her debut as privat-docent of the course of general pathology at the Faculty of Bologna. The young doctress was received with great applause.

A wealthy Saxon promised his physician half his fortune if the doctor cured his wife. He did so, and now the doctor is suing for the promised reward; the husband's gratitude having evaporated in the usual manner as the wife got better.

An eight-year-old boy, of Cleveland, O., showed symptoms of arsenical poisoning after smoking cigarettes. A dealer in tobacco stated that arsenic was put into the wrappers, or coverings, of the cigarettes, to make them burn brilliantly and evenly.—*Sanitary News.*

The medical profession of America is represented at the International Congress of Therapeutics and Materia Medica, to be held in Paris next August, by H. C. Wood, Bartholow and Meade Smith. Where, oh where, do Boston, New York and Washington come in?

We are pleased to announce that Dr. Ménière's health has been sufficiently restored to permit him to renew the publication of the *Gazette de Gynecologie.* We extend congratulations to our French confrère, and welcome the reappearance of his valued journal upon our table.

Dr. Sutton's private hospital, Terrace Bank, makes the following report: In the last fifty abdominal sections made for ovarian tumors and otherwise diseased ovaries and tubes, but three deaths occurred. In the last thirty-six cases there was one death; in the last thirty cases no death.

The smallpox has broken out in Oklahoma. It would be a thoughtful and humane act if every reader of The Times and Register who has any reliable vaccine virus to spare were to send it to the new territory. Send to the Mayor or the Postmaster at Guthrie, and request him to give it to the physicians.

The Bombay government has prepared a bill providing for village sanitary boards, each consisting of three persons, chosen by the collector. Their duties are limited to arranging the water supply, street cleaning, abating nuisances, and generally promoting sanitation. If voluntary subscriptions are insufficient for their expenses, a tax will be imposed.—*Indian Med. Gazette.*

Eye Photography.—Faiese Green, a British photographer, has actually produced a picture with only the light issuing from his eye. Having stared for fifteen seconds at a 3,000 candle electric arc only three feet away, he closed his eye and quickly brought it over a sensitive plate at a distance of one inch. The result was a very faint but distinct image of the arc and the carbon, due probably to a momentary phosphorescence of the retina. A second attempt fa led, and gas lights proved too weak to produce an effect.—*Am. Analyst.*

[We prefer to let Mr. Greene risk his eyes on such experiments; we reserve ours for safer work.]

THE NEW M.D.

He has just come out of college,
With his head crammed full of knowledge,
So he thinks! So he thinks!

He has come the world to alter,
In reform he'll never falter,
So he thinks! So he thinks!

And he'll banish all old fogies,
Just like a lot of bogies,
So he thinks! So he thinks!

In a few year's he'll grow tired,
And won't act like one inspired,
So he won't! So he won't!

He will learn life's hard and dreary,
That the world ain't run by theory,
Yes he will! Yes he will!

He will then grow very prudent,
And he will laugh at the young student,
Yes he will! Yes he will!

And he'll say, I once was really
Very green and very meally,
Sure's you live! Sure's you live!

—*From Dr. Heeter's Scrap Book.*

An International Congress of Otology and Laryngology will be held in Paris, September 16 to 21, in the Trocadero Palace. Those desiring to present papers should forward the titles of their communications before July 15, to the secretary of the committee of organization, Dr. Loewenberg, Rue Auber 15, Paris.

The Morris Canal, running from Jer ey City to Philadelphia, is about to be abandoned, as it is no longer a profitable means of transporting coal. This means that the locks are to be broken and the water let out of the levels, uncovering many acres of low land which has been under water since 1832.

Physicians along the line of the canal had better lay in a goodly stock of quinine.

A farewell dinner was given to Dr. J. C. Greenawalt, by the Pennsylvania Railroad officials at Westville, on April 27. Dr. Greenawalt has been Medical Examiner for the Pennsylvania Railroad Relief, at Camden, since its organization, and leaves the service to engage in practice at Chambersburg. He was presented with a full set of surgical instruments, medicine cases, and other equipments by his late associates and friends.

Lately we noticed in a foreign journal an account of the removal of a foreign body from the ear. It was a pearl, perfectly round and smooth, filling up the external meatus completely. The physician finally extracted the pearl, using a delicate pair of forceps made for the case. We recollect once reading of an American surgeon who, called to a similar case, displayed much greater ingenuity. He stuck the end of a match into some glue, put it in so as to touch the foreign body, and waited till the glue set, when he withdrew the body without difficulty. The natural query is, whose glue did he use? We won't tell till next week; and if our glue makers don't take the hint by that time, they're too slow to do business in this world.

WHAT "ENGLAND" CONSIDERS JOKES.

This little German word is worth remembering. It signifies the "bursting of a water pipe:" Hoehquellenwasserlieferungszohrenfatalitaten.

A Maine girl didn't want a lover to name a boat after her, because she didn't desire to read in the papers, that "Matildy Slocum is in the dock to have her keel scraped."

"My brethren," said Swift, in a sermon, "there are three kinds of pride—of birth, of riches, and of talents. I shall not speak of the last, none of you being liable to that abominable vice."

A man married a girl who brought him a child in six weeks. His friends rallying him, and saying the child had come too soon—"You are mistaken," answered he; "it is the ceremony which was too late."

The best toast of the season was, I think, given by a printer, viz.:

"Woman; the fairest work in all creation. The edition is large, and no man should be without a copy."

If there were only three women in the world, what would they be doing? Two would be sitting together scandalizing the third.

And if there were only three men in the world, what would they be doing? Looking after those three women.

"Were you wounded in the Crimea, Pat?"

"No, yer honor; the bullet hit me in the chist and kem out at me back."

"Why, Pat, that would have gone right through your heart."

"Och, faix, me heart was in me mouth."

The illustrious traveler looked contemptuously at the mountains. "Nothing very high about here," said he, scornfully.

"Make out his bill," said the landlord, turning to his clerk, and in five minutes the traveler was inquiring the shortest way to the lowlands.

"I don't see why you should sneer at my engagement ring," said one girl to another of her acquaintance; "it's far prettier than the one you wore three years ago and have not worn since."

"No, dear," replied the other, with a cool, faraway look in her eyes, "not prettier, but quite as pretty. It is the same ring."

A case of rather unusual surgery recently came under our cognizance. The patient had a hard chancre, and enlarged glands in both groins. The surgeon removed both the superficial and the deep glands. They were not suppurating and their removal was with a view of preventing systemic infection. Secondary symptoms, however, developed in the usual time and manner. We do not recollect having heard of this operation being done, or even suggested, previously. If any of our readers know of a similar case we would be pleased to hear of it.

Surgeon Franklin Bache Stephenson, United States Navy, who at a recent session of the American Academy of Arts and Sciences was elected a Fellow in the Section of Philology, is a native of Western Pennsylvania, and was at one time a student in the Allegheny College at Meadville, and from which he graduated with honors in 1870.

While he has been honored at home his worth was appreciated abroad, for some time since he was enrolled a "*membre titulaire de la Société d'Anthropologie de Paris.*

The April issue of *The Trained Nurse* (consecrated to those who minister to the sick and suffering in hospital and home), contains articles on The Relation of Hospitals to Medical Education; Insanity, its Causes and Cure, Articles for the Mother's Use, Health in Our Homes, Asepsis for the Nurse, besides considerable other editorial and original matter. The monthly Hospital Supplement contains the latest hospital news from all parts of the world. Only magazine of its kind in this country. Lakeside Publishing Company, Buffalo, N. Y.

Yellow fever has already reappeared in Florida. Look out for this summer. Surgeon-General Hamilton has done wisely by calling the attention of the government to the prevention of smuggling, as by that means the fever germs are imported. Now let the people of Florida do their part, by putting their towns in such a hygienic condition that they will be secure, even if the disease is introduced. Nothing pays so well in a community as sanitation. The Florida towns are not too large to be manageable, and the problem is, after all, a simple one. Modern methods of drainage and disposal of sewage are fully capable of protecting the towns, if the people have intelligence to utilize them.

Joseph H. Rotherman, a carpenter of Connellsville, has on the back of his neck a birthmark, crescent in shape and bluish in color. When the moon is turning its first quarter the mark becomes reddish and begins to swell. As the moon grows older the mark becomes redder and the flesh swells correspondingly. When the moon is full the crescent on Rotherman's neck is bright red and the flesh assumes a horn-like roll over two inches in thickness at the largest part, gradually tapering to a point on the shoulder. As the moon wanes the mark decreases in size and color until it again becomes a bluish crescent-shaped mark.

[What strange things a man sees when he has no gun!]

A New York judge has given his opinion that a person who practises medicine under the title of homœopathist, has no right to use anything but the homœopathic system upon his patients. In other words, his object is not simply to cure his cases, but to cure them if they can be cured by homœopathy.

One of their journals contains an item stating that a cancer patient who had been given up as hopeless by Dr. Agnew, was recovering under homœopathy. We recollect another patient who had been under the latter system, but it failed to cure her, and two weeks before her death she sent for a physician. He gave her a dose of morphine. Her comment was characteristic. She said: "I never knew it was in the power of medicine to give such blessed relief." That was the verdict of thirty years experience under homœopathy.

Bathing in Japan.—In the prefecture of Hyogo, the regulations respecting mineral springs were promulgated, the principal points of which were as follows: Occupancy is to be for three purposes, namely, for bathing, for drinking the waters, and for selling the waters to be drank; care must be taken to secure the admission of good air and sunlight to the bath-rooms; in private bath-rooms the mixed bathing of males and females above ten years of age is forbidden, except for one or two families, or in the case of fellow visitors; a table of analysis and a statement of medicinal value, and a notice as to the mode of bathing and drinking must be posted in each room, and the neighborhood must be kept clean; those who prepare baths in other places by carrying thither spring water must change the water daily; those who sell the water for drinking purposes must paste a label on the vessel giving the name of the spring, its medicinal value, directions for use, and address of the seller.—*Sei-i-kwai.*

Army, Navy & Marine Hospital Service.

Changes in the Medical Corps of the U. S. Navy for the week ending April 27, 1889.

Wilson, Geo. B., Assistant-Surgeon. Detached from the Naval Hospital, Mare Island, and ordered to the "Iroquois."

Cordeiro, F. J. B., Passed Assistant-Surgeon. Detached from the "Vandalia," and ordered to the Naval Hospital, Mare Island, Cal.

Bransford, John F., Surgeon. Ordered to the "Iroquois."

Stitt, Edward R., Assistant-Surgeon. Ordered to Bureau of Medicine and Surgery, Washington, D. C.

Fereber, N. M., Surgeon. Ordered to Naval Academy, Annapolis, Md., for examination of candidates for admission to the Academy.

Origin of Tetanus.—In a rather lengthy communication regarding tetanus, to the French Academic de Médecine, Professor Verneuil arrives at the following conclusions: microbic nature of the malady; origin chiefly derived from the horse; transmissible from horse to man and from man to man; the contagion from the animal to man, or from man to man, may be direct or mediate, but more often direct. A large number of cases bearing on this subject are duly quoted, and in all one of the following causes were noticed: 1. Contagion from a horse suffering from the disease. 2. Wounds produced by healthy horses may also convey the contagion. 3. Wounds produced by objects serving or having served for horses infected or healthy have caused the disease. 4. Infected manure. 5. The earth brought into contact with the infected animal. 6. The microbe of this disease remains latent until the skin is broken. 7. Air containing the dust of stables, etc. Further, an author claims that since the introduction of the antiseptic treatment of wounds this disease is seeming more rare.—*Bulletin de l'Academie de Médecine.*

MEDICO-LEGAL CASES.

BY HENRY A. RILEY, ESQ.,

NEW YORK CITY.

THE Albany *Law Journal* is one of the humorous journals, though the casual reader would hardly expect to find in its pages anything except dry legal lore. It is a fact, however, that its editorial columns contain some of the brightest and sharpest comments on current events to be found in any paper of the day. Take, for instance, its statement of the physical perils the wayfarer in our streets incurs when he ventures forth from his home, and it will be readily conceded that the account has both humor and truth in abundant measure. The writer describes the perils of winter, and then says: "Instead of snow balling there is the base ball playing nuisance maintained by small boys, without pay, in imitation of men who play ball for salaries larger than those allotted to most of the judges.

"Instead of coasting, or 'bobbing,' there is the swift and stealthy bicycle, as deadly as the ancient war chariot, running people down, or, at least, causing the nervous man to jump to one side like a tarantula. Then a school of sweet little girls on roller skates swoops down upon us, making it dangerous to turn either way, and compelling us to stand still and see our salvation.

"Our neighbor's coal-hole is open or insecurely covered, and one leg slips in or both heels fly out, with woe to brittle bones. There is the peel of orange or banana dropped upon the flagging in disregard or defiance of our statute in that case made and provided. There is the danger of the whip-lash, flourished by the profane driver of overfreighted wagon, or stuck out at conventional right angle over the sidewalk by the liveried lackey upon the carriage box, threatening loss of eyesight, or a mark on the cheek like a sabre slash in a German student duel. We bruise our legs in climbing over skids stretched across the walk, or we barely dodge a box or barrel, or one of those pasteboard safes spoken of by the funny man of the *Times* falling from a hoistway.

"A rickety sign endangers our head, or a low wire our thought. We stop to chat a moment with a friend and lean against a deadly charged electric pole, and it is all over with the conversation. A passing plumber burns our coat with his unextinguished hand furnace; a passing carpenter lacerates our trousers with a saw; a passing porter imperils our head with a long piece of gas pipe on his shoulder. One is annoyed, if not endangered, by the servant washing the sidewalk by a hose, or the fireman carrying his wriggling serpent up a ladder. A fresh, young Italian maid from Cork, with a white muslin nightcap on her head, runs us down with a baby carriage, scarring our shins or necessitating a visit to the chiropodist. Then, there is the woman's um-

brella that wasteth at noonday, scooping us up after the manner of a drag net, or impaling us in its blind and headlong charge.

"All these are sidewalk perils. If we undertake to cross the street dangers multiply. The pedestrian has no rights which the driver is bound to respect, and the footfarer, unless a handsome woman personally conducted by a big policeman, will be subject to being run down by the driver of a beer wagon, or a physician in a hurry, or the chief of the fire department on his 'golomping' way to a conflagration, or a coroner intent on beating a rival, or a belated voter standing out till the last moment for his price, or even a hearse on its business way back from the grave.

"Runaway horses are another source of midway perils, and so are wagons turning around corners with long irons or beams projecting from behind. This list might, perhaps, be increased, but these common instances show that man walks the city amid perils scarcely less than those of the desert, the sea, the forest, or even the battlefield; almost as deadly as those encountered and enumerated by St. Paul.

"Most of them, indeed, are 'perils by false brethren' against which the injunctions and penalties of the law are futile. To avoid misapprehension, we will add that these lines are not written in the interest of any particular accident insurance company."

The first case in the courts in regard to the peculiar practice of clairvoyant physicians comes to us from Wisconsin, and is of peculiar interest. The plaintiff in this case brought an action for malpractice for improperly treating his son.

The testimony showed that the clairvoyant's mode of diagnosis and treatment consisted in voluntarily going into a sort of trance condition, and while in such condition, giving a diagnosis of the case and a prescription for the ailment. He did not make any personal examination, and did not endeavor to ascertain the past or present condition of the patient, and, indeed, he did not profess to have been educated in the science of medicine.

The answer to the charge was that the clairvoyant employed the usual methods of his class, and could not, therefore, be liable for malpractice, as it was understood how he treated his patients. The judge was asked to charge the jury as follows: "If the defendant was a clairvoyant physician, and professed and held himself out to be such, and the plaintiff and his parents knew it, and at the time he was called to treat the plaintiff both parties understood and expected that he would treat him according to the approved practice of clairvoyant physicians, and he did so treat him, and in strict accordance with the clairvoyant system of practice, and with the ordinary skill and knowledge of that system, then the plaintiff cannot recover, and your verdict must be for the defendant." The judge declined to make such a charge, but was willing to direct the jury by making the last clause read, "with the ordinary skill and knowledge of physicians in good standing, practising in that vicinity, then the plaintiff cannot recover, and your verdict must be for the defendant" This ruling was not satisfactory to the clairvoyant, but was affirmed on appeal, as was also the verdict adverse to him. The court held that it was not good law for any person to claim immunity against a charge of malpractice simply because he practised a peculiar kind of medicine. The physician must have reasonable knowledge of his profession, and have ordinary skill. If a person goes into a trance, and then prescribes without any personal examination of the patient, he does so at his own risk. This view will be regarded as eminently sound by the great mass of the community who do not practise medicine but are practised upon.

One of the most remarkable medico-legal cases which we have seen in a long time comes to us from a Georgia court, but as no statement is given of the facts upon which the legal decision is based the reader cannot judge as to the extent of the injury referred to. The question was whether the Georgia code made the wilful and malicious injuring, wounding, or disfiguring of the private parts of a female a crime. It was conceded that the code made these acts upon the male a crime, and the court struggled with the question whether the female was entitled to an equal protection. The decision was to the effect that the shield of the Georgia code was held equally over the male and female. The court says: "It would be simple nonsense for us to hold that in contemplation of law a female has no private parts. And why should we conclude, that having them, they are less protected by law against being injured, wounded, or disfigured than those of the male."

In a recent Texas case a husband brought suit against the Western Union Telegraph Company for damages on account of a failure to deliver a message from him to a physician, asking him to attend his wife in her confinement.

The messenger called twice at the doctor's office, and not finding him, made no further effort to deliver the message. In the meantime plaintiff's wife gave birth to a still-born child. The suit was decided against the company, but exemplary damages seem to have been awarded to a considerable amount, and this was considered by the appellant court to be error, and the judgment was reversed. The basis of the decision is as follows: "We do not think that the death of the child before birth, and the grief or sorrow occasioned thereby, can be an element of damages in this character of suit. If it is made to appear from the testimony that Mrs. Cooper suffered more physical pain, mental anxiety, and alarm on account of her condition than she would have done if Dr. Keating had been in attendance upon her, and the failure to secure his service is shown to be due to the want of proper care on the part of defendant's servants, whose duty it was to deliver the message, a fair and reasonable compensation should be allowed for such increased pain and mental suffering; but the death of the child, the bereavement of the parents, and their grief for its loss, cannot be considered as an element of damages."

The New York Legislature has before it a proposition to remove the insane from a number of county institutions to the State asylums, and there has been

considerable opposition manifested, though not from quarters where it should have weight. The State Board of Charities has recommended the change as certain to result in better care for a class of unfortunates which is steadily increasing in all the States, and all the medical societies which have taken any action at all have also advised the change. There is probably no one who has looked into the matter at all impartially who has not come to the conclusion that the change is desirable, but on possible grounds of economy, and because there is considerable political patronage belonging to the present system, there has been developed considerable opposition. It is most desirable that the proposed plan shall receive the assent of the Legislature, and this now seems very probable.

EPICYSTIC SURGICAL FISTULA FOR CYSTOSCOPIC EXPLORATION:

INTRAVESICAL TREATMENT AND DRAINAGE.

(Read before the State Medical Association of Alabama, April 11, 1889.)

By JOHN D. S. DAVIS, M.D.,
BIRMINGHAM, ALABAMA.

EPICYSTOTOMY has become an established and frequently practised procedure, and the dangers incident to opening the bladder through the abdominal wall is so slight that patients suffering from almost any vesical trouble are encouraged to have the bladder opened for diagnostic purposes and treatment at a time when the general health remains unimpaired; a practice which, a few years ago, would not have been resorted to by the most aggressive surgeon.

Catarrh of the bladder, irrespective of its cause, is alway followed by a series of consecutive pathological changes which, independently of the partial or complete interruption of the passage of urine, tend to destroy life. A dilatation of the bladder and ureters by retention of urine may give rise to such a degree of distention as to destroy life from suspension of important functions by mechanical pressure. During the stage of inflammation a paretic condition may occur, the bloodvessels in the vesical wall lose their support, and transudation and exudation take place into the paravascular tissue, which, combined with capillary stasis attending this stage of the disease, results in sloughing, infiltration, pyæmia, peritonitis, and death. The damming up of the urine may, and does often, cause surgical-kidney, epididymitis, and tetanus.

The treatment of chronic vesical catarrh resolves itself into a consideration of the causes producing the disease, many of which, the presence in excess of certain inorganic constituents of the urine, stone, stricture, and hypertrophy, are capable of correction; while others—such as malignant tumors and certain conditions of the prostate—may only admit of a palliation of the symptoms to which they give rise, and the removal of which must be the first object in treatment. But when a paretic condition of the bladder exists provision must be made for the complete continuous emptying of the viscus; its thorough cleansing by frequent irrigation with hot sterilized water; and the promotion of a healthy tone in the mucous membrane and muscular structure of the bladder. The frequent introduction of catheters for drawing off residual urine and washing out the bladder has been productive of much harm, and, instead of giving relief, proved to be, by reason of their frequent introduction into the inflamed bladder to draw off the urine two or three times a day, a source of immediate and alarming symptoms. These facts are cogent reasons for adopting surgical means in all cases of intra-vesical troubles as soon as a diagnosis can be made, and often when it can not otherwise be made, for the complete emptying of the bladder, thorough cleansing, diagnosis, and intra-vesical treatment.

The epicystic surgical fistula is designed for drainage, intravesical treatment, and cystoscopic exploration, and may be divided for consideration under the following heads:

I. Definition of epicystic surgical fistula.

II. Surgical resources in the formation of the epicystic surgical fistula.

1. Preparation for the operation.
2. Anæsthesia.
3. Position.
4. Incision and opening bladder.
5. Intra-vesical exploration and treatment.
6. Toilette and after-treatment.

III. Advantages of the epicystic surgical fistula.

1. Cystoscopic exploration.
2. Intra-vesical treatment.
3. Drainage.

I. DEFINITION OF EPICYSTIC SURGICAL FISTULA.

Epicystic surgical fistula is the title here given to a supra-pubic fistula into the bladder created by the surgeon for exploration, intra-vesical treatment, and drainage. A fistula, which, acting as an artificial urethra, is capable of giving free access to the inside of the bladder for cystoscopic exploration, to provide a ready, convenient, and comfortable means of emptying the bladder at will, and gives the surgeon a competent opening into the viscus for intra-vesical applications.

It constitutes an essential element in the speedy and complete evacuation of the contents of the bladder in all epicystic operations, and imitates nature in the restoration of its own continuity and repair as the pathological changes within the bladder subside.

II. SURGICAL RESOURCES IN THE FORMATION OF THE EPICYSTIC SURGICAL FISTULA.

1. *Preparation for the Operation.*—The presence of two assistants, though not necessary, may be of valuable aid. A temperature of 80° or 85° F., should be maintained in the operating room from the beginning to the end of the operation. All hair is to be shaved from the pubis, and all the details of antiseptic surgery are to be carried out so far as cleaning the pubis and abdomen. The bladder is emptied and thoroughly washed with warm water. When the water returns clean the bladder is slowly distended with warm sterilized water thrown into the bladder by means of a fountain syringe, with nozzle in urethra—a degree of pressure sufficient to distend the bladder to its utmost capacity—which can never be too great for the resistance of the bladder. It is better to fail in

filling this viscus than to distend this viscus beyond the limit of competency. Indeed, it is not necessary to fill the bladder to any degree of resistance. I have operated when the bladder was in an irritable condition and would not tolerate distention greater than the capacity of two ounces, and had no difficulty in avoiding the prevesical fold of peritoneum or finding the bladder. The water is secured in the bladder by tying the penis at the base with a rubber tube.

A colpeurynter is next to be well oiled and inserted into the rectum—the rectum having been previously emptied by enema—and filled with warm water. This distention brings the bladder into view above the pubis.

2. *Anæsthesia.*—My preference for chloroform is the result of my own personal experience with it. It is not free from objections, as its depressing effect on the heart is well known. The operation usually occupies fifteen minutes; and, hence, its prolonged use would be unnecessary and uncalled for. The objection to ether is the suppression of the excretions and the frequency with which bronchitis is produced when administered to persons advanced in years. The best course to pursue, when the operation is prolonged, is to follow the use of chloroform by ether. The patient must be kept profoundly under the influence of the anæsthetic from the first incision until the superficial wound is closed.

3. *Position.*—The patient is placed on the back on an ordinary operating table, with the legs extended as if in a position for perfect comfort and rest. Many surgeons claim advantages in the position recommended by Trendelenburg. Eigenbrodt emphasizes the fact[1] that the elevation of the pelvis in Trendelenburg's position[2] helps the surgeon to avoid the prevesical peritoneal fold at the time of the incision of the bladder.

I have employed this posture for intravesical operation by means of the supra-pubic incision with no advantage over the ordinary flat-back position. With two openings in the bladder, for a continuous stream of clear water, I have no trouble in illuminating every part of the bladder with the electric surgical light, being thus enabled to examine the entire intravesical wall. Undoubtedly the position recommended by Trendelenburg possesses advantages which to the author more than myself, makes it highly ideal. As for myself I prefer and recommend the flat-back position.

4. *Incision and Opening Bladder.*—A perpendicular incision three or four inches long is made in the median line above the symphysis pubis. The recti muscles are separated to the symphysis. If the pyramidales are in the way, the fibres should be cut. The transversalis fascia is divided on a grooved director from symphysis to within one inch of upper margin of superficial wound. Instead of following Guyon's manœuvre, I catch the bladder with a tenaculum on a line with the symphysis, through the prevesical fat, and cut through with a bladder knife into the bladder with one smooth, clean incision, to prevent undue disturbance of the cellulo-adipose tissue between the bladder and pubis and avoid infiltration. I have never seen a case where it was necessary to put up the prevesical fat, and with it the peritoneal cul-de-sac. If the bladder is caught on a line with the symphysis and cut downwards, no fears need be had for the peritoneum. Cutting this prevesical fat prevents its after dropping down over the opening into the bladder and acting as a valve to prevent easy escape of urine and causing infiltration. And, too, such a procedure gives a smooth incision throughout, and it is almost impossible to have infiltration, even when no drainage-tube is left in the bladder and the urine is left to flow out through the fistulous track and taken up by a layer of absorbent cotton. In making the incision into the bladder, no attention is to be paid to any vein or veins which are sometimes met with. If cut, they will stop bleeding when the bladder is dropped back and the rectal bag removed. The operation is usually bloodless in the sense of hemorrhage. I have operated without the patient losing more than one drachm of blood.

5. *Intra-vesical Exploration and Treatment.*—The finger is carried into the bladder and a thorough search made for any tumors, villous growths, or foreign bodies. The bladder is now emptied and the rubber around penis united and the bladder well washed out with hot sterilized water. The bladder can now be examined with the cystoscope and surgeon's electric light. If tumors be found, they should be removed; if practicable villous growths and any foreign body found should be removed. If nothing is found in the bladder, the surgical fistula, in the absence of malignancy, will be all that is required to relieve the cystitis.

6. *Toilette and After-treatment.*—The bladder is allowed to drop back into the pelvis and the superficial wound so closed by two sutures (including the skin and superficial fascia only), in the lower portion of the incision and one in the upper portion of the incision, as to leave a fistulous track of equal size from bladder to juncture of upper third and middle third of the superficial incision. A large rubber catheter is now to be introduced into the bladder through the opening and its distal extremity allowed to enter a urinal placed in the bed between the patient's thigh, or, preferably, at the patient's side. Prof. F. Trendelenburg, Director of the Surgical Clinic of the University of Bonn, proposed, for draining the bladder in supra-pubic lithotomy, the T tube in latero-abdominal position and open wound treatment as the simplest, safest, and best. He makes an antiseptic dressing of iodoform gauze around the T tube. There can be no real necessity for a tube of any kind to be introduced into the bladder for the purpose of conveying the urine from the bladder to prevent infiltration, irritation of superficial fascia, and soiling of dressings.

If the urine is kept acid, by the administration of citric acid or some other more palatable acid drink, no better antiseptic than the acid urine can be secured for the constant bath of the parts. It should be al-

[1] L. c., p. 72. Cf. Lang, *Med. News*, December 4, 1886.

[2] In Trendelenburg's position the patient's legs are held over the shoulders of an assistant with the body resting on an incline table, much in the position which hogs are swung for spaying.

lowed to flow out through the wound and absorbed by a pad of absorbent cotton placed loosely over the wound, and removed as often as soiled by the outflowing urine. By this method of emptying the bladder, no possible small amount of urine can be impeded in its outflow, which is the case around and outside of the tube, when catheter or tube is left in for any length of time—a source of no little annoyance at times. This little collected or retained urine, around the outside of the tube alone, I have seen produce a hard chill and elevation of temperature, and become for the time an immediate, alarming and aggravating source of trouble. I never have seen the skin made sore or chafed by the outflowing urine in epicystotomy, or from its after escape through the surgical fistula.

The bladder should be washed out twice daily with hot sterilized water, by means of a fountain syringe, with its nozzle introduced into the urethra, the water escaping through the epicystic fistula and guided into a bed-pan under the patient. The superficial stitches are taken out at the end of a week, and intermittent catheterization by the fistula is then resorted to for the sole purpose of draining the fistula and preventing rapid closure. It is not necessary to catheterize for the purpose solely of drawing off the urine. In one case I never drew the urine save for the purpose of analysis, but occasionally introduced a rubber bougie to prevent the closure of the fistula. The drainage by the fistula alone is admirable, and the fistula will be well formed in twenty or thirty days, competent to retain urine without dripping and to allow its escape in a good projecting stream at will. With no tearing of the tissues, and with a clean cut, the drainage is perfect and the dangers are *nil*.

III. ADVANTAGES OF THE EPICYSTIC SURGICAL FISTULA.

1. *Cystoscopic Exploration.*—Nitze has by means of the cystoscope been enabled to diagnosticate tumors of the bladder in nine cases in which rectal palpation, the sound and other means had furnished negative results. One of the great difficulties in the cystoscopic exploration of the bladder is the presence of pus, mucus, and sometimes blood, which renders it exceedingly difficult to maintain a translucency of the fluid used to distend the bladder. By means of a simple fountain syringe a constant current of clear water may be kept within the bladder, so essential to a complete observation of the trigonum Lieutaudii, the most interesting part of the viscus, the ureters, and to examine any affection of that viscus. The fistula may be made for temporary purposes of cystoscopy by the Peterson-Guyon-Perier operation; but I can see great advantages from a different operation, by Dr. Hunter McGuire, the object of which tends to eliminate as well as detect the trouble within the viscus; and, too, in the final construction of a permanent fistula, gives an easy after-method of exploration, and makes a better artificial method by reason of its length and extension upwards of two to three inches. Diagnostic purposes are met by the possibility of immediate detection of all local conditions, such as tumors, calculi, foreign bodies, neoplasms, the collection of fluids from the ureters, etc.

2. *Intra-Vesical Treatment.*—Having by means of the epicystic exploration revealed the true nature of the intra-vesical trouble, the treatment resolves itself into the immediate necessities of the case. For instance, prostatectomy may be necessary, villous papilloma may be found and should be remedied; pedunculated growths may be found which should be removed by the scissors or Paquelin's cautery, etc. In such cases, the opening in the bladder sufficient to introduce the finger, should be enlarged downwards under the symphysis pubis and the operation indicated should at once be performed. The object of the formation of the permanent surgical fistula is to meet the after indications in such operations, the detail of which does not properly come within the province of this discussion. However, it is sufficient to state, what is reasonable and practicable, that a better means by which the intra-vesical wall can be reached and treated therapeutically has not yet been devised.

3. *Drainage.* — Permanent after-drainage in all intra-vesical operations can not be necessary; but is highly essential to secure good and sufficient drainage until the paravascular tissue is disengorged, the cystitis is relieved and the urine becomes normal and passes per urethra unobstructedly. And until this end is attained complete artificial arrangements for the escape of the contents of the viscus must be made. In such cases of prostatic hypertrophy or malignant growths, when removal of the obstruction is impossible or contra-indicated, the epicystic surgical fistula is clearly indicated and essentially necessary. It meets every possible indication for local treatment and gives the only controllable, ready and free drainage to viscus and kidneys. Urinary back pressure as the result of incompetency of the urethra from the various immovable prostatic troubles is often an immediate and remote cause of surgical kidney, which can only be removed or relieved by supra-pubic drainage. It is indicated in other conditions of the bladder, of long standing cystitis; as in the case reported by me in the *Virginia Medical Monthly*,[1] in which the urethra, though made competent by cutting, was not sufficient to keep the bladder emptied without catheterization—a procedure which kept up a constant vesical inflammation, which, combined with capillary stasis attending the inflammatory process resulted in paresis.

I now have the pleasure of introducing to you that case, Mr. T. A. Nixon, fifty-eight days after the operation. His condition to-day is sufficient guarantee for all I have said in favoring the formation of an epicystic surgical fistula for the relief of chronic vesical catarrh. The result in this case is more than I promised. He can retain his urine several hours and without dripping of urine or pain to bladder. The urine is completely under control and his bladder is relieved of pain.

Two hundred and seventy-eight patients were admitted last year to the New York Cancer Hospital.

SIMULTANEOUS AMPUTATION OF BOTH ARMS—RECOVERY.

(Read April 10, 1889, at the Philadelphia County Medical Society.)

By W. W. KEEN, M.D.,
Professor of Surgery, Woman's Medical College of Pennsylvania.

FOR the notes of this case I am indebted to Dr. J. C. Heisler, then surgical interne at St. Mary's Hospital, and it is put upon record as a contribution, at least, to the statistics of multiple amputations.

Paul K., aged fifteen years, was run over by a street car, at 5 o'clock P. M., on November 13, 1887. He was admitted to St. Mary's Hospital two hours later. The right hand, forearm, and elbow, as well as the left hand and lower part of the forearm were crushed; both clavicles, also, were fractured.

The boy had lost a great deal of blood before his admission, and was in profound shock when admitted; so grave was his condition that it was doubtful whether he would live through the night.

My colleague, Dr. J. B. Roberts, saw him late in the evening, and ordered whisky and digitalis. At 10.45 o'clock P. M. his temperature was 97°; his pulse 120.

The next morning the temperature was 102.5°; pulse 142. At 1 o'clock P.M. his condition was very grave, but, as he had rallied from the shock, I decided to give him the only chance of his life by amputating both arms. The right arm was amputated below the insertion of the deltoid; the left forearm at its middle. The moment that the first amputation was done, during the dressing of that arm by my assistants the second was proceeded with, so as to lose as little time as possible. He bore the ether badly, and his pulse at times was almost imperceptible. Almost no blood was lost during the operation, the arm being Esmarched above, but not including the crushed parts. Of course, the most careful antisepsis was carried out. There was no need for hot bottles, etc., as his temperature was well maintained. From the time of the operations his recovery was a perfectly steady one. For the first three days the morning and evening temperatures were about 100° and 102° respectively. From that time on it fluctuated between 99° and 100°, reaching the normal by the tenth day.

On the third day after the operation the anterior flap on the left forearm began to slough; by the end of a week a piece two inches transversely by half an inch in the axis of the limb was completely separated. The gaping wound now exposed the end of the radius covered with granulations springing from both the periosteum and the medulla. In order to promote adhesion of the flaps extension was applied to them by means of adhesive strips, on which traction was made by a rubber band. This band extended to the end of a straight splint applied to the forearm, counter-extension being maintained also by adhesive plaster which was tacked to the upper end of the splint. At the end of two weeks the lips of the wound were united, and the splint was taken off. The right stump healed kindly, all the sutures being removed by the twelfth day. The boy was up ten days after the operations, and was sent home six days later to come to the hospital as an out-patient until he was entirely well. He was finally discharged at the end of January. Two small circular sequestra separated from the ulna and the radius of the left stump, and were removed January 9 and 24. The recumbent posture was the only treatment used for the fractured clavicles. They united very well, and with but little deformity.

A CASE OF LAPAROTOMY FOR EXTRA-UTERINE PREGNANCY.

(Read at Allegheny County Med. Society, March 19, 1889.)

By X. O. WERDER, M.D.,
PITTSBURGH.

AT the November meeting of this Society I reported a case of extra-uterine pregnancy in which I had performed abdominal section with a successful result. To-day I present the specimen of my second case of tubal pregnancy, removed by laparotomy, on February 14, of this year.

The history of this case is, briefly, as follows:

Mrs. M., twenty-seven years of age, married, two children, the youngest sixteen months old, has been suffering with periodical attacks of severe abdominal pains for almost a year, for which she several times required medical treatment. During the five or six weeks preceding the operation, these attacks increased in frequency and severity, making her unfit to do her ordinary household duties. Walking almost always produced a great deal of suffering. On January 26, of this year I was consulted for one of these attacks of pain, which was referred to the pelvic region, principally the left side. Making a vaginal examination, I found the uterus enlarged to the size almost of a two-months' pregnancy and to the left of this, in the region of the left tube, a soft, extremely tender mass, which was slightly movable. A careful bimanual examination could not be made on account of the very great sensitiveness of these parts. She had menstruated regularly every four weeks during the last eight or nine months, and was at this time still nursing her baby. At the two subsequent examinations I found no change in her condition, except, perhaps, that this tumor was slightly larger than before. The diagnosis was not quite clear, but I was inclined to the opinion that it was either a hydrosalpinx, or a pyosalpinx, more probably the latter. As her suffering at times had almost become unbearable, I advised laparotomy, to which she readily consented, but the operation was deferred until after her next menstrual period, which was now very close at hand. Menses lasted five days, and presented nothing unusual. In the afternoon of February 13, the day preceding the operation, she came from her home to my office in a carriage, for the purpose of going to Mercy Hospital. On examination I found her condition unchanged; the mass, however, seemed now decidedly larger. The riding on the rough country road from her home did not seem to have caused her as much suffering as expected, and she was cheerful, and feeling better than for several days previously. But on her way to the hospital the pains returned in unusual severity, and she arrived there faint and nearly collapsed. Several hypodermic injections

of morphia made her more comfortable, but she continued very sick and sore all night. On my morning visit before the operation she looked very pale, and was very feeble, still suffering considerable pain. Vaginal examination was not made.

On opening the peritoneal cavity dark blood escaped from the wound, and the abdomen was found containing a considerable quantity of blood, liquid and coagulated. In reaching down for the sac, on the left of the uterus, I felt a small rent in it, probably one-half inch long, which, however, in trying to bring it to the surface, was enlarged, so that all its contents escaped into the abdominal cavity. The bleeding was now very free, the blood being bright red, and easily distinguishable from the old dark blood already contained in the abdomen. The sac was now tied off, and the clots contained within the pelvic cavity turned out. After washing out the abdomen with hot distilled water, it was closed, leaving, however, a glass drainage tube. Blood continued to discharge from this tube for three days, when it was removed.

The patient rallied very nicely from the operation, and made an uninterrupted recovery, her temperature and pulse remaining perfectly normal after the fourth day. She left the hospital on the twenty-first day, and is now in good health.

Rupture of the tube must have taken place on her way to or at the hospital, probably as a consequence of the jolting of the carriage. This evidently was the cause of the faintness and slight collapse after her arrival at the hospital the evening before the operation.

Comparing the histories of the two cases operated on by me, we find the first case an almost typical one of ectopic pregnancy, and one of comparatively easy diagnosis to one at all familiar with this interesting anomaly, while the second case is as atypical as possible, in which I claim a diagnosis to have been entirely impossible, for there was not the slightest reason to even suspect a pregnancy, as the patient had been menstruating regularly, her last catamenial period terminating just a few days before the operation, and she was still nursing her baby at the time she came under observation.

This case illustrates again the great difficulties in diagnosing extra-uterine pregnancy, and I cannot agree with Hanks, when he states that the diagnosis can be made in at least 95 per cent. of cases. The case also demonstrates that this interesting affection is by no means such a very rare condition as some seem suppose, as this is the second case occurring in my own practice within the period of four months. That this was a case of tubal pregnancy there could be very little doubt, but in order to be perfectly certain, I sent the specimen to Dr. William H. Welch, of Johns Hopkins University, Baltimore, for examination, and he verified the diagnosis. The specimen, he states, consists of an ovary, part of a Fallopian tube, the intervening broad ligament, the fœtal membranes and a placenta with umbilical cord.

THE French are going to send out medical missionaries.

Hospital Notes.

MEDICO-CHIRURGICAL HOSPITAL.

(Clinic by PROF. FRANK WOODBURY.)

CHRONIC CATARRHAL PNEUMONIA.

THE first case presented was that of a married woman aged thirty-eight years, a Belgian by birth. The patient had been in good health up to the time when she had arrived in this country, a year and a half ago. Ever since that time she had been ailing. She complained of persistent cough with purulent expectoration, loss of flesh and night sweats. About a week previous to her appearance at the clinic she spat blood for the first time, and according to her statement the hemorrhage was rather free. She had, in addition, some digestive difficulty and was constipated. Examination of the lungs revealed the existence of dulness on percussion at the right apex, with bronchial râles, feeble inspiration and prolonged expiration. The percussion note on the left side was normal, but there was evidence of increased action, probably supplemental. The lecturer pointed out that the case had many points of resemblance to tubercular phthisis, viz., the night sweats, the hemoptysis, the loss of flesh, and the persistent cough, but he did not think that it had been due primarily to tubercular infection, because, although the disease had existed for more than a year, the other lung had not been attacked. Since hemoptysis had appeared, it is probable that tubercular infection had recently occurred. He said that before arriving at a final conclusion the sputum would have to be examined for bacteria. In the mean time he was disposed to regard the case as primarily one of catarrhal or broncho-pneumonia, due either to climatic changes in this country, or to the fact that the patient had caught a severe cold on shipboard; the chronic catarrhal pneumonia resulting from bad treatment and hardships endured since arrival in this country. With regard to treatment he said: It is not always judicious to check the cough in these cases unless it exhausts the strength of the patient or causes much loss of sleep, as the cough is simply an effort of nature to get rid of the bronchial secretions which act as a foreign body and cause irritation. So far the cough is conservative; should, however, it become excessive, the following combination will be found useful:

℞.—Acidi hydrobromici dil.
Syrupi pruni Virginian. . . . . āā f℥j.—M.
Sig.—A dessertspoonful to be taken at bedtime.

To each dose of this it may be necessary to add a few drops of deodorized tincture of opium. At the same time a tonic plan of treatment is to be adopted, *i. e.*, cod-liver oil and the hypophosphites; with generous diet, fresh air and attention to general hygienic conditions. For relief of the hectic, I know of nothing better than salicine in fifteen grain doses about an hour before the fever comes on; the patient being instructed to lie down for one or two hours in the afternoon. Quinine having failed to prevent the regularly recurring attacks, when given on the sup-

position that they were due to malaria, is said to be of no use in hectic, but it is valuable as a tonic, especially in the combination recommended by Niemeyer. Climatic treatment is of great value in these cases, and, I think, possibly, if this patient could afford to return to her native land where she always enjoyed good health, or to select in this country some inland climate in every respect similar to that from which she came, she would be materially benefited by the change. She has been taking five drops of creasote three times a day for the past two weeks with decided reduction in the amount of sputum expectorated.

CHRONIC ASTHMA ASSOCIATED WITH ROTARY LATERAL CURVATURE OF THE SPINE.

The next case shown was that of a man aged forty-five years, a day laborer by occupation. He gave the following history: He had been troubled with asthma since childhood, the attacks being frequently paroxysmal; he said he "had them whenever he caught cold," or after exposure at his work, as he was much subject to the influences of the weather from the nature of his occupation. There was no marked family history of asthma, though he stated that a first cousin had suffered from the disease. Examination showed that the chest was long and narrow with falling in of the lower intercostal spaces. The heart's impulse was most evident in the epigastric region, the apex beat being felt in the sixth intercostal space, nipple line. The first sound was weak, and the apex beat was lacking in force, but there was no evidence of valvular disease or hypertrophy. There was probably some right-sided dilatation of the heart. The lungs were hyper-resonant anteriorly, and upon examination posteriorly the patient was seen to have rotary lateral spinal curvature in the upper dorsal region with bulging of the ribs on the left side, with corresponding sinking in of the chest wall on the right side in front. The lecturer thought that this deformity was due to an attack of pleuro-pneumonia in early childhood resulting in pleural adhesions. Evidence of venous stasis in the head and limbs was well marked. The prognosis was considered to be unfavorable as to complete recovery, but a great deal could be done to improve the general condition of the patient and shorten his attacks. He advised flannel clothing, with avoidance of cold as far as possible, the patient being especially careful not to work in damp clothes. As to internal treatment the following mixture was prescribed:

℞.—Tinct. belladonnæ . . . . . ♏x.
Syrupi pruni Virgin. . . . . ʒi.—M
Sig.—To be taken every three hours.

Locally, he said hot fomentations and poultices to the chest or dry cups at the beginning of the attack would be useful, with inhalation of the fumes of burning nitre paper; stramonium and belladonna cigarettes, and the smoking of an equal quantity of tobacco and dried stramonium leaves in a small room, so that the fumes could be inhaled. As there was no pain in the back and the deformity was of such long standing, he did not consider it necessary or advisable for the patient to wear any form of orthopædic apparatus.

LATERAL MUSCULAR SPASM FROM OVERWORK IN A WEAVER.

An interesting example of the class of affections known as professional dyskinesia, or anapeiratic paralysis (Hammond) was next presented. The patient was a carpet weaver, aged thirty-five years. His occupation compelled him to use his right side exclusively,—the arm being employed in throwing a shuttle, and the leg in pressing a treadle. About a month ago, after having been overworked and worried a good deal, the patient began to lose control over the muscles of the right arm and leg, rhythmic contractions being developed whenever he attempted to work. Later he found the rhythmic movements coming on at other times when he was not working. These spasmodic attacks were somewhat influenced by the will, the patient being able to control them by a mental effort. There was some loss of power in the affected muscles, but no evidence of atrophy or impaired sensation. The left side was entirely unaffected. The lecturer remarked that recovery was impossible as long as the patient continued to work, and that in order to obtain a cure absolute rest from work at the loom was essential. Much benefit would result from cold douching with massage and weak galvanism to the affected muscles. The patient was advised to take a sea voyage as a favorable opportunity for his doing so had occurred.

INTERNAL HYDROCEPHALUS WITH SPONTANEOUS OPENING IN THE OCCIPITAL REGION.

A case of unusual interest terminated the clinic. The patient was a female infant aged three months, and had the following history. It was born at full term of healthy parents after an easy and natural labor. The child was well developed and healthy until it was a month old, or two months previous to its appearance at the clinic, when the mother noticed a small swelling on the back of its head, which burst, and discharged a thin, clear fluid, occasionally tinged with blood. The discharge continued for nearly a month, then a poultice was applied with the result that the opening closed up and the discharge (which was never more than a teaspoonful in the twenty four hours), ceased. Soon after this, or about a month ago, the child's head began to enlarge uniformly, the infant becoming fretful, unable to move its head, and losing flesh. There was much restlessness at night with marked nystagmus, but no convulsions. The appearances were characteristic of congenital hydrocephalus. After reviewing the pathology and clinical history of the case, the lecturer said the treatment should be directed towards preventing further enlargement of the head, and, if possible, removing the existing fluid. The first object might be attained by equable pressure of the head with strips of adhesive plaster or a bandage. It was pointed out that this procedure should not be adopted in cases when the head rapidly increased in size for fear of producing compression of the brain. It was proposed to tap the ventricles and draw off enough of the fluid to relieve tension. The method he preferred was capillary aspiration. This could be accomplished by inserting a hypodermic needle to which was attached

a long rubber tube filled with antiseptic solution (a syphon being thus improvised) and drawing off a few drachms at a time. The lecturer mentioned that he had used this method with success in the treatment of pleural effusion and ascites. When the child was first seen two days ago, it was very fretful, refused to nurse and had vomiting of mucus. It appeared as if on the verge of convulsions, and was given:

℞.—Hyrarg. c. cretâ . . . . . gr. xij.
Sacc. lactis . . . . . gr. xxiv.
M. et in chart. xii divid.
Sig.—One to be taken four times a day.

The mother was instructed to nurse the baby regularly every two hours, and if her milk was not retained by the child to feed it with cow's milk diluted with lime water. This plan of treatment was carefully carried out and the mother reported marked improvement in the child's condition. The powders were discontinued, and the following ordered:

℞.—Potassi acetatis . . . . . gr. ij.
Elixir aurantii . . . . . ♏ xv.
Aquæ . . . . . q. s. ad ℥j.—M.
Sig.—To be given every four hours.

The child was also ordered beef peptonoids, to be given with the milk and lime-water three times a day. Warm salt water baths were also advised.

CEREBRAL SYPHILIS.

Waugh presented the following case: May 1, 1888, J. D., aged twenty-four. He had a hard chancre seven years ago, followed by sore mouth, but no syphilides or rheumatism. Fifteen years ago he had a discharge from the left ear, which continued until two years ago. This was followed by pain over the left ear, with the sensation of a swelling at the left parietal eminence. He had spasms in his right arm, beginning two weeks ago, followed by motor and sensory paralysis, which lasted only a few minutes. He was also speechless. Four such spasms occurred half an hour apart. Consciousness was only lost in the first spasm. The arm has never fully recovered. The spasms recurred on five different days, affecting the arm and the right side of the face. The general health is good, the digestion is normal and he sleeps well. Slight numbness has been felt in the right foot, and later in the left arm. The upper part of the left tympanum is opaque, cerumen dry, audition $\frac{24}{40}$. Right ear, $\frac{12}{40}$. The right tonsil is enlarged; the left nostril is obstructed by a deviated vomer and some hypertrophy. There is slight paresis of the left internal rectus. He has also stenosis of the aortic valve, with slight regurgitation; an ulcer in his mouth, and his hair is becoming scanty.

There was some question as to whether the symptoms were due to the constitutional disease or to the affection of the ear. The rapid improvement which ensued when the protiodide of mercury was given (¼ gr. four times daily), settled the diagnosis. This patient has now taken the drug persistently for one year; but when he drops it for a few weeks the symptoms begin to return. Three years is the time for which Waugh ordered the mercury to be continued.

LAPAROTOMY—DEATH.

Two years since the patient had been attacked by septicæmia after the premature birth of a seven months' child. This was followed by pelvic cellulitis, and that in turn by pelvic abscess. During these two years there had been recurrent attacks of cellulitis. At the time she came under Montgomery's care, examination showed the presence of fluid in the anterior part of the abdomen, as high up as the umbilicus; and pelvic abscess was diagnosed. An incision was made in the ordinary manner. Upon opening the abdominal cavity it was found that the sac of peritoneum enclosing the abscess was adherent to the parietes of the abdomen. The contents were removed, but in spite of the fact that the patient's temperature remained normal, her system was so depressed by reason, probably, of the absorption of pus for so long a period, that she progressively weakened and died in the course of a few days.

Where there is extensive pigmentation of the skin in cases of pregnancy Stewart gives sodii phosphatum ʒi, in hot water, every four hours until there is a free evacuation of yellow feces. He then substitutes ℞. acidi sulph. aromat. ♏x, Donovan's solution ♏iij–v. Misce. Sig.—Take ter die. Watch cautiously the action of the arsenic.

For a shooting neuralgic pain in the forehead, Stubbs recommends, ℞. Extracti belladonna, gr. iij; extracti hyoscyami, gr. vi. Misce et fiat in pilulas, No. 12. Sig.—Take one pill every three hours.

Shoemaker recommeds the use of beta naphthol, given in ¼–½ gr. doses, in pill form, three times a day, in chronic or obstinate cases of constipation. It is antiseptic and makes the stools of a clay color. "This is a new remedy, and in my hands I have obtained the best results from it in all cases tried by me."

As a tonic Prof. Pancoast gives: Ext. ignatiæ amaræ, gr. ⅓, quininæ sulph., gr; ½, ferri pyro-phos., gr. i; piperiu, gr. ⅙; pulv. cinnamom, q. s. M. et fiat pulv. unum. Given after each meal.

A case of spina bifida, in which there was incontinence of urine and general muscular debility, was presented to the class as cured by Prof. Pancoast, who had made several applications of an iron at white heat over the spinal column at the lumbar and sacral regions.

In ozena, Pancoast uses, ℞. Acidi borici, ʒi; tr. myrrhæ, fʒi; mellis, fʒii; infus. cinchonæ, fʒiij; aquæ ad., fʒiv. Misce. Sig.—Use as gargle and wash. After using the wash, apply with the finger: ℞. Hydrarg. chlor. mitis, gr. viii; ung. aquæ rosæ, ʒi. Misce et fiat unguentum. Sig.—A piece the size of a pea to each nostril.

Prof. Stewart gives absolute relief in every case of eczema capitis of young children, by giving liquor arsenici et hydrargyri iodidi, ♏ss ter die, after meals. Cleanse the head thoroughly, and apply unguentum picis liquidæ.

PHILADELPHIA HOSPITAL.

DR. SINKLER.—My attention has recently been called to the treatment of locomotor ataxia by suspension, as practised by Prof. Charcot. It consists

simply in suspending the patient for a limited time, by means of an apparatus that will throw most of the body weight upon the head and spinal column. The Sayre apparatus of New York, which was primarily used for the application of plaster-jackets, was used; but, having some objectionable features about it, Dr. S. Weir Mitchell of Philadelphia improved upon it, and it is now my privilege to show and demonstrate its practical use to you. It consists, as you see, of a horizontal rod of steel or iron, the extremities of which are turned upward in the shape of a hook. At the center of the rod is a ring by which the whole apparatus may be suspended from a beam or ring in the ceiling by means of a pulley. From each extremity straps drop, and end in a cup-shaped support for the elbows,—this being somewhat different from the Sayre apparatus, which throws the support in the arm pit. Straps also drop from near the centre of the rod in such a manner that a cup-like depression is made for the chin and another for the occiput, all being held firmly in position on the patient by means of other straps, which should be adjusted so that the weight of the body will rest on the elbows and head piece. Having done this, raise the patient slowly by means of the pulley until his feet do not touch the floor. This throws the body's weight on the elbows and spinal column, which causes a strain on the ligaments of the spine and a consequent elongation. By having the patient extend his elbows from his side all the weight is thrown on the head piece, causing a greater strain. As to the duration of the suspension, great care must be taken, for it is injurious to suspend longer than three to four minutes at one time, while at first thirty seconds is sufficient, until he becomes accustomed to it. Avoid fatiguing, exciting or roughly handling the patient, and when the treatment is ended require quiet and rest. Of course it is not supposed that one of stout build can be handled like one of lighter weight, for his weight would cause more strain. Do not suspend the patient more than every second or third day. Prof. Charcot claims to have had many good results from this method of treatment, as used in several hundred cases, and although you cannot expect to accomplish *absolute* cures from it, yet the marked improvement of coördination and standing in many cases has led to a thorough test of its merits in this institution.

In cases of pyuria renalis, due to calculus, Dr. Walker recommends, ℞. lithii carbonatis gr. iij; acidi borici gr. iij–v. Misce et fiat pil. No. i. Sig.—Four times a day. He thinks the free use of lithia waters renders the urine alkaline and prevents calculi from forming; boric acid prevents fermentation of urine, and promotes antisepsis; while free use of water flushes the kidney and often washes calculi away. The combined action prevents chills. Examine carefully for urethral stricture.

Astringent washes prevent the formation of bed sores. A 1 per cent. solution of chloral hydrate, in the hands of Dr. Walker, gave very beneficial results in treatment of bed sores. The parts were thoroughly syringed, washed and dressed in chloral. If a bed sore is large and has a "lazy look," cleanse it thoroughly and dress with red cinchona bark, ʒi to the ℥i. Cleanse all sores with corrosive sublimate, 1–2000; or boric acid.

Dr. Walker treated, with recoveries in almost every instance, several hundred cases of so-called threatening typhoid, in which there were persistent frontal headache, furred tongue, biliousness, tendency to constipation and abdominal tenderness. ℞. Calomel, gr. $\frac{1}{12}$, ipecac, gr. $\frac{1}{12}$; or ℞. Calomel, gr. $\frac{1}{12}$; sodæ bicarb. gr. ii; sugar of milk, gr. i. Misce, fiat pulvem. Sig.—To be given every four hours until patient has a good passage. Discontinue this, then give for seven days: ℞. Quiniæ sulph., gr. iss; caffeinæ, gr. ss. Misce et fiat pulv., No. i. Sig.—One ter die.

Society Notes.

INDIANA STATE MEDICAL SOCIETY.

FORTIETH ANNUAL SESSION, HELD AT INDIANAPOLIS, MAY 1 AND 2.

DR. W. H. WISHARD, President, of that city, in the chair.

THE President's Address was a retrospect of the practice of medicine for the past half century. He considered this period one of great progress in science as well as other things. The great thing is, have we as medical men kept abreast with the times. He endeavored to make his answer convincingly in the affirmative. The primitive Indiana doctors had not great advantages of education. In 1817, the Transylvania University, at Lexington, Ky., opened a medical department, and in 1818 John L. McCulloch was the first graduate in medicine west of the Alleghenies. This soon grew to the second medical school of the United States. In 1819, the Medical College of Ohio, at Cincinnati, and in 1837, the medical department of the University of Louisville were formed. Not 10 per cent. of the physicians of Indiana, in 1825, were graduates, and only 20 to 25 had taken one course in medicine. Ephraim McDowell was not a graduate, but after thirty years of practice the University of Maryland gave him the honorary degree of doctor of medicine. There was but one medical journal in the United States in the early part of this century, the *Medical Repository* of Philadelphia. Obstetric business was all in the hands of females. It was necessary; physicians were scarce. Women were healthy, and nature needed but little aid. Such an affair was quite a celebration to the female portion. Not to be invited was a great slight. The physicians were looked upon with suspicion in this line of practice, and were not summoned unless there was great necessity. When summoned the news spread like wildfire and the neighborhood turned out *en masse*, as though it was a funeral or a wedding. A log cabin 12 x 14 would be literally packed by women and children, with sometimes a few men. Early settlers were almost exempt from tuberculosis, diphtheria, and cerebro-spinal meningitis. Only the strong and healthy ventured to the front. In winter pleurisy and pneumonia raged.

The doctor was a dealer in second-hand goods. Four-fifths of the fatal cases had been treated by the old women till the case was hopeless. He well remembers when quinine first came into use. He was given a prescription consisting of thirty grains of quinine, ten drops of dil. sulphuric acid, and six ounces of water. Dose, teaspoonful to be taken three times a day with great care. He has known an old thumb-lancet to descend as an heirloom from the father to son and grandson, and had drawn more blood than some regiments in the late war. An old theory was that if you would draw blood from the right arm when the pain was in the left, you would draw the pain across the heart and kill your patient. The curtain was first lifted in the treatment of fevers by Dr. Lunsford P. Yandell, of Louisville, and the light has been shining more and more ever since. He thinks the domain of surgery has made wonderful progress in the last fifty years. The good dame of fifty years ago would show her ten or a dozen sons and daughters, the pride of her life, the hope of her future. To-day we are shown one son or daughter and a poodle dog, often only the poodle dog, all the hope of this family. The Doctor then paid some scathing tributes to criminal abortion, and went on to discuss the fortieth anniversary of the Indiana State Medical Society; organized June 6, 1849; twenty-eight physicians were present, of whom now only five are living; four in Indiana and one in Texas.

Dr. King, of Indianapolis, related the incident of his father and mother both dying within seven minutes of each other, from being bled forty years ago, only a few miles from Indianapolis.

Dr. Leech, of Indianapolis, spoke on criminal abortion, and told an interesting story of how he saved two twin girl babies, and what pleasure he derived by seeing them playing on the hillside as he drove past their home.

Myxœdema, with report of case, was the subject of a paper read by Dr. Jas. F. Hibberd, of Richmond, Ind., at the meeting of the Indiana State Medical Society. His patient was a lady, aged fifty, previously slight in build, but although her general health had been failing during several months, her weight was 143 pounds when she consulted him. She suffered from a sense of general weariness, abatement of mobility, disinclination to active exercise, and lessened ability to concentrate her mind on any important affair. Her skin had become dry, pale, and sallow, and was swollen and puffy, particularly about the feet and hands; but gave her most discomfort from the thickness and weight of her eyelids and surrounding tissues. Her limbs had lost their normal suppleness, and she walked with an unsteady gait; her hands were stiff and swollen, making it almost impossible to hold a pen or write. She complained of general subjective cold, and her temperature was found subnormal. She presented a depreciation of vital activity and a sluggishness of mental operations. Examination displayed no special error in respiratory, circulatory, urinary, or uterine functions.

The patient was advised to cease her literary occupations; moderate outdoor exercise, with quinia, strychnia, and iron soon brought a slow improvement in her condition, though she still presents a remnant of her serious ailments of two years ago. This is a typical case of myxœdema, a mild attack, of favorable progress and promising prognosis, but presenting all the characteristic symptoms of the disease.

The first description of myxœdema was by Gull, in 1874; and in 1876 Ord gave a thorough exposition of its leading characteristics, and proposed the name, as he declared mucin was found in the tissues of all its victims. Hammond gave a short description of the disease in 1881, and the treatises on general practice since have had chapters devoted to myxœdema.

The *American Journal of Medical Sciences* published two papers in July and August of 1888, by Drs. Hun and Prudden, giving thorough details of four cases under their observation, and of the literature of the subject. Excluding cases due to the extirpation of the thyroid gland for diseases, and those associated with idiocy and cretinism, there are one hundred and thirty-four cases of idiopathic myxœdema, more or less completely reported according to their researches.

The conclusions reached by them are: there are more than three times as many females affected as males; the average age for the beginning of the disease is forty years; chief etiological factors are excessive child-bearing, excessive hemorrhage, mental shock and worry, and injuries, especially of the head. Myxœdema appears to manifest itself by very characteristic symptoms, which affect, especially, the cutaneous, nervous, and vascular systems. Cutaneous: Skin swollen without pitting, dry, scaly, and cold; hair and teeth frequently fall out. The mucous membranes are swollen, but their secretion is increased, while perspiration is absent or greatly diminished. Nervous system: Mental sluggishness and impairment; insanity frequent; impairment of sensibility in most cases; in all cases muscles act feebly; numbness and neuralgic pains are often present. Muscular system: Pulse usually slow and small, and heart presents some abnormality. Blood often in an anæmic condition, sometimes severe hemorrhages. A clear, succinct, comprehensive statement of our present knowledge of this disease is found in the summary of Dr. Ord, printed in the London *Lancet*, June 2, 1888, and copied in the *Medical News*, Philadelphia, June 23.

The author concludes with the statements that he thinks myxœdema a distinct disease, with well-marked symptoms; its diagnosis is easy and certain; it is not amenable to treatment, and persons affected with the disease never regain a perfectly normal condition. He thinks it quite possible to meet associated disturbances with remedies, and by proper use of exercise and rest to carry persons through years of comparative ease.

Urethral Stricture in the male was considered by D. W. N. Wishard, of Indianapolis. He followed Otis' classification and location of stricture. He discussed the subject of electrolysis in stricture, but was unsatisfied in his own mind, and at present he finds no method as successful as the Otis operation. It is the only method in which he feels confident in curing the

stricture. Absence of fatal or even serious resulst have led him to consider it a safe method, though he avoided operating in cases of kidney trouble.

Nervous sick headache was the subject of a paper read by Dr. A. G. Porter, of Lebanon, vice-president of the society. Concerning this disease he said little was written, little known, the treatment was unsatisfactory and the disease very frequent. He thought 99 per cent. due to a deficient supply of blood to the brain or some part of it. An ounce of sherry wine or brandy in a glass of soda water was good in many cases where there was a chill and depression present, but in many others it was inadvisable. Valerian and asafœtida are very good, or two or three drops of dilute hydrocyanic acid, and an emetic if the stomach is at fault. We must abridge hours of study or work.

Dr. Howe, of Richmond has cured several cases when due to stomach trouble by bismuth and fluid extract of quassia.

Cholecystotomy was the subject of a paper by Dr. Miles F. Porter of Fort Wayne. He favored the continuous suture after Tait's method. A case of Suppurative Peritonitis was the subject of a paper by Dr. G. W. McCaskey, of Fort Wayne. Glaucoma by Dr. A. Blitz, of Indianapolis.

Nature and Etiology of Tuberculosis was the subject of a paper by Dr. H. F. Stone, of Indianapolis. He did not believe in the theory of contagion and opposed bacteriology and all the ideas of Koch.

Dr A. W. Brayton, of Indianapolis, admired the doctor's courage to write such a paper as this time, and it took courage to make such antiquated statements.

Dr. Theodore Potter, of Indianapolis, considered tuberculosis inoculable, and the only cause the tubercle bacillus of Koch. Where the tubercle exists the bacillus exists, and we have in the tubercle bacillus a positive diagnosis of tuberculosis. If the tubercle bacillus is excluded by a careful examination we can exclude tuberculosis. Not to believe in the tubercle bacillus we might as well not believe in the spermatozoids which made us.

Dr. Stone, in reply wished to be put on record that he was opposed to this fallacious theory of germs. It is a myth. "I do not believe in antisepsis only so far as it induces cleanliness."

The secretary's report showed a gain of six County Societies and seventy members over last year. The mortality list was not a lengthy one but included two ex-presidents, Drs. W. H. Field and Benjamin Newland, also Dr. Moses Baker. of Stockwell, the first surgeon in Indiana to perform ovariotomy, and Dr. Mary Thomas, of Richmond, the first female doctor to become a member of the Society. About eighty out of the one hundred Counties in the State have County Societies, and all members of the State Society. A man cannot be a member of the State Society unless membership in the County Society makes him a member of the State Society. The fees are paid to the County Society and the names and fees turned into the State Society. For $1,00 a man becomes a member, and receives the transactions. The society is the largest and most thoroughly organized State Medical Society connected with the American Medical Association. It can be safely said that in the near future public opinion will compel every physician to unite himself with the State Medical Society, thus to sustain the honor and dignity of the profession and rebuke charlatanism and obtrusive effrontery under whatever guise they may appear. The whole number of members is now 1,200. The treasurer's report showed the financial affairs of the society in a prosperous condition.

Dr. Lomax, of Grant County, at the meeting of last year proposed a plan for the improvement of the Indiana State Medical Society. It was for the County Medical Societies to secure the pauper practice in the counties and donate the fees paid to the college. The duties of the pauper practice could be done by the members in turn and would not be hard on any one. The committee reported adversely to this proposition for the reasons that the State Society could not well manage a large well-endowed college, as a vast amount of competition and rivalry would arise among the applicants for faculty and managing positions, and everything would be in confusion. Then the County Societies could not get the pauper practice in all cases if they tried. There were many irregular physicians and so many regular ones who do not belong to the County Societies that they would underbid the County Societies. The committee also reported that in Indiana there are 3,243 regulars or allopaths, 287 eclectics, 199 homœopaths, 142 physiomedicals and 105 unclassified. Less than one-third of the regulars are not connected with the County Societies.

The committee on ethics had some delicate matter to attend to which was handled with all due care and tact. A committee appointed for that purpose endorsed the National Formulary.

Dr. Kate Corey, a graduate of Michigan University, and superintendent of the Methodist Hospital at Foochow, China, was introduced to the society and made a brief speech. Her great work was related by the secretary and a motion to make her an honorary member was passed without a dissenting voice.

The Committee on Ethics asked the appointment of a committee to draw up some uniform rules by which a member shall be tried by the County Societies. The request was granted.

Dr. E. S. McKee, of Cincinnati, was introduced as delegate from the Ohio State Society, and delivered a message of good will and greeting.

Officers elected: President, Dr. J. D. Gatch, Lawrenceburg; Vice-President, Dr. S. T. Yount, of Layfayette; Secretary, Dr. E. S. Elder, Indianapolis; Assistant Secretary, Dr. T. C. Kennedy, of Shelbyville; Treasurer, Dr. F. C. Ferguson, Indianapolis.

Antiseptics in Normal Labor was the subject of a paper read before the Indiana State Medical Society at Indianapolis, by Dr. G. W. H. Kemper, of Muncie, Indiana. The doctor had attended nine hundred cases of labor in civil practice, and in no one instance had he used a single antiseptic measure before or after parturition. Two of these women died, one of puerperal convulsions and the other of acute pneumonia. He had no case of severe puerperal fever among his nine hundred cases. The cases

were of the average gravity as proven by the particulars which were given. He had some cases which would have demanded the antiseptic treatment if any did. They did not get it and recovered all the same. If he had used that treatment what encomiums he could have bestowed upon the practice. A class of recent converts to antiseptics charge that all who do not avail themselves of this practice are criminally negligent. The health officers report in Delaware County, the county in which the writer resides, gives a ration of 7.5 deaths per 1,000. This includes the practice of doctors, midwives and old women. Ten out of the 34 deaths were due to accidents which could not be affected by antiseptics, which presents a more favorable outlook than the hospital practice of the larger cities with antiseptic precautions,

He considered the paraphernalia and details of antiseptic midwifery as laid down by Thomas, Garrigues and others, to be both expensive and tiresome. He had without the formality of an introduction witnessed a number of deliveries within five minutes from his entry into the house. In such cases the time for the ante-preparatory antiseptic treatment of Prof. Thomas would not equal in opportunity that of a death-bed repentance, of a subject of Judge Lynch. While he would do something towards antiseptics where it seemed necessary, yet he would not feel it advisable in every case of normal labor when a patient is surrounded by healthy environments to attempt to carry out a complicated routine of practice which his experience teaches him is uncalled for.

The doctor in conclusion submitted the following aphorisms :

1. The history of obstetrical practice teaches us that the lying-in hospital has always been a place of danger and mortality, therefore, it is obligatory on those who have charge of those institutions to utilize every antiseptic measure known to the profession to save life.

2. The experience of country practitioners teaches us that women who are confined in healthy isolated rural homes are not subjected to the contaminating influences of an ochlesis, and consequently do not require all the precautions of those exposed to hospitals, or even to the atmosphere of city life.

3. That the country practitioners of medicine will generally show a lower rate of mortality in obstetrical cases than city practitioners, simply for the reason that they practise in healthier localities and less exposure to contagious influences, and possibly have a healthier class of patients.

4. That the insinuations of a number of late writers on antiseptic midwifery, that the death rate in obstetrical practice of country practitioners is high, are not true as shown by statistics.

Broncho-pneumonia in children, was the subject of a paper by C. W. VERNON, M.D. of Indianapolis. He used this term purposely because he meant it and thought it the proper term. He thought the burning of natural gas in this city had become a great factor.

The houses had been kept too warm and dry. Mouth breathing was also coming to be a prominent cause. He thought the disease occurred more frequently among children than adults. The disease may commence in the tubes and extend into the alveoli, and *vice versa*, or may commence in the interstitial tissue. In treating the measles, whooping-cough, etc., we should keep under consideration the possibility of this disease.

DR. JOHNSON, of Indianapolis, was pleased that the doctor insisted on the term broncho-pneumonia. He thought there were more recoveries from acute lobar pneumonia than from broncho-pneumonia, as the latter is apt to be neglected by the patient. Dr. G. V. Woolen would only criticise the doctor in one point, and that is, he scarcely went above the epiglottis or larynx in his genesis of the trouble. He thought the whole life of the respiratory organs was to be found in the head at the back of the brain. Catarrhal disease he thought essentially a disease of childhood ; no man in this body who has not catarrh already will ever, in his opinion, acquire it.

The Hydro-Therapeutic Treatment of Typhoid Fever, was the subject of a paper by DR. G. W. SMYTHE, of Greencastle, which was followed by a paper on Atypical Typhoid Fever, by DR. MCCULLOUGH, of Ft. Wayne. He thought irregular typhoid fever much more frequent than generally supposed.

DR. M. F. PORTER thought there were more cases of the atypical typhoid fever than the typical. Authors of text-books he thought had made a great mistake. He opposed the general routine treatment of typhoid fever by cold baths, yet he thinks cold baths in a great many cases are beneficial.

DR. LEECH thought the great question was, are you capable of diagnosing a case of typhoid fever.

DR. LOMAX, of Grant County, has been studying typhoid fever for a long time, but could not give a good definition of it. It had been thought that the disease should be given a name having some connection with the spleen. He considered the classification of Trousseau into adynamic, ataxic and typhoid fevers the best.

DR. MENDENHALL, of Richmond, said there were three hundred thousand cases of typhoid fever in the United States each year, and thirty thousand of these die. "We ought to be interested in this disease. We can never know exactly how to treat it until the disease is understood, and I believe we do now understand it. I believe it is caused by germs. When we can kill or stop the production of these germs the cause will be gone and the disease stop. If we give quinine we will get trembling, nervous conditions and hallucinations. If we leave off this and tonics, we will not have so much of this kind of trouble." Early in the disease he gives small doses of calomel or bichloride and turpentine oft repeated. Two drams to one pint of turpentine emulsion and two grains of calomel. He does not use antipyretics.

The discussion on this disease grew quite lengthy, and a gentleman rose to a point of order, saying we were already far behind the programme. The President replied that he knew it, and we were leaving typhoid fever about where we found it. Dr. Smythe in replying said the whole question was one of diagnosis. Will we permit our patients to die of secondary troubles or not? He uses Von Ziemssen's graduated bath, and gives quinine in forty-grain doses, having given as high as seventy grains.

IMMUNITY FROM SPECIFIC FEVERS.

BUCHNER (*Medizin. Zeitung*) discusses this interesting question of immunity and protection in specific fevers. He defines immunity in its widest sense as embracing those bodily conditions which resist the inception, or neutralize the activity of any animal poison brought within the sphere of infection. These are firmly established by a single attack of the fever, which exempts the same subject from a second attack of the same fever. We are disappointed to find that the author has no better theory to advance in accounting for immunity than the old, illogical, and absurd one of the preëxistence in the body of some specific principle, which has been put there for no other purpose but to be destroyed by the specific poison of disease. The nomenclature differs somewhat, but the theory remains the same. He calls the hypothetical substance a "specific" ptomaine, which is neutralized by the specific poison, the body remaining "neutral" thereafter.

We cannot avoid the conviction that attacks of specific fever leave effects more lasting than is generally supposed. A severe typhoid fever causes a diminution of vital power, which may be felt throughout the remaining life of the subject. Looking beneath the fallacious sensation of well-being, which often leads convalescents to speak of the fever as leaving them in better condition than they have been for years, we invariably find a diminution of the power of exertion, an impairment of bodily and mental vigor, a lessened capacity of resisting fatigue, exposure, and other noxæ. The condition of the body resembles that of a country after an exhausting war; and, like it, the devastation may be so great that the pristine strength is never restored.

Ten years ago, Buchner propounded his views as to the nature of specific diseases; and the influence of inflammation in combating the bacillar operations. Proofs of this hypothesis are daily unfolding themselves and confirming his earlier opinions. He then showed that the inhalation of splenic fever bacilli set up a sero-fibrinous pneumonia. As the result of recent experiments, he says that the inflammatory reaction stays the progress of the bacilli invading the surface of the lung, and bring about a degeneration of the bacteria preparatory to their destruction.

Schickhardt obtained similar results. Microscopical examination also shows that as soon as inflammation begins, the bacteria degenerate and die.

Ribbert and Lahr injected *staphylococcus aureus* into the trachea, and noted that the local inflammation stopped the ingress of the bacteria and caused their destruction.

Temporary immunity, Buchner believes to be due to the presence of a chemical compound in the blood, which prevents the development of the invading bacteria. When this substance is exhausted, the period of incubation is past, and the blood is then a suitable culture medium for the bacteria, whose systemic effects are then first manifested.

The whole subject is still shrouded in obscurity, which, however, we may expect to see dispelled in the near future.

A TIME TO CLEAN.

WHETHER the recently reported case of yellow fever in Sanford, Fla., turns out to be a genuine case of that malady, or simply one of bilious malarial fever, the lesson it teaches is the same. It should be taken as a warning of what may be expected this summer. The prevalence of yellow fever last fall must have left the germs of the pestilence in many places, ready to spring into activity after the requisite period of hot weather has elapsed. Although the type of the fever was mild, it is not unusual for these epidemic affections to develop their full virulence in the second season, after they have become acclimated, as it were, and the multiplication of the germs has intensified their power. But there is no reason why Florida towns should have yellow fever if they choose to take proper precautions against it. The problem is comparatively simple. An efficient system of drainage, proper disposal of sewage and garbage, and a pure water-supply are the three requisites; while the establishment of quarantines, the disinfection of suspicious clothing, or of localities, and other measures of a like nature, come in at a distance from those first named, in the order of importance. And yet the tendency seems universal to ignore these first principles of sanitation, and to rely upon those measures which have over and over again been proved to be but broken reeds. Garbage crematories are especially suited for tropical towns, where there is a need for speedy destruction of putrefactive substances. The system of treating sewage by electricity has been favorably reported upon in England, and is deserving of investigation. If a plentiful supply of pure water cannot be procured for a town, its site is not suitable for habitation, and it should be transferred to a more eligible locality. It is said that Florida has been much altered socially by the in-

flux of Northern settlers, with Northern energy and money. If this be true, now is the time to show it; and if Florida appreciates the financial returns to be derived from investments in sanitation, there is no reason why she should not become the garden of America.

AFTER reading in the *Weekly Abstract of Sanitary Reports* the condition of Live Oak and Lake City, Florida, we feel like paraphrasing the holy writ by saying that "he who reads may run."

Though these two towns are situated in close proximity to last year's yellow fever district, and have every reason to fear another outbreak of that dreadful scourge, their condition must closely approximate that of Italian villages during the Middle Ages. Yet the inhabitants take their afternoon siestas in that land of flowers as unconcernedly as if sanitation were a delusion, and yellow fever a bugaboo, a mere name, a nothing, and not a fatal fact. Here is an excerpt from the report of United States Sanitary Inspector, J. L. Posey:

"In the central part of the town of Live Oak the practice is tolerated of allowing the sewage from the county jail to flow into a small marshy pond a few yards distant, which, during the summer drought, becomes dry, leaving the fecal matter exposed to slow evaporation, necessarily producing a very unwholesome atmospheric condition. The topography of the town is such that the surface drainage flows into several small lagoons, which are situated in the corporate limits, and doubtless supply ample morbific material for the development of the various types of malarial fever which prevail during the summer and autumn. Little attention is paid to the systematic removal of garbage and contents of open closets, and as a result the water supplied by wells of no great depth furnishes types of typho-malarial fever, which usually prevails."

This condition of affairs would not greatly surprise us in Kamtschatka or Patagonia, but it is most decidedly astonishing to hear of it in Florida, a state in which the inhabitants have had such warnings as ought to cause them to take three-fold precautions, and not be acting as if they were Hindoo fatalists instead of educated Americans.

With regard to cemeteries the inspector says:

"It is a subject of surprise to me that so little foresight has been exercised in nearly all the smaller towns of Florida in the selection of sites for cemeteries. In view of the porous nature of the soil and the general use of well-water, it would appear a matter of ordinary prudence to locate the burial plot at least a mile from the corporate limits of a town, but the usual site is in the town proper or just beyond its boundary."

This custom is not confined to Florida alone. The first object that greets one in visiting many a little town in Pennsylvania, is the cemetery, the site for which is almost invariably a hill which the village abuts, and which is apparently so chosen that the water from it may drain into the village wells.

Herodotus tells of a tribe of Scythians, whose custom it was, when a member of the tribe had survived his usefulness, for the immediate family to collect together in order to give their aged relative the last testimonial of affection. A large cauldron of water was set boiling, and when the steam rose and the water bubbled merrily, the most loving son took the liberty of killing his father, after which the less favored relatives assisted in separating their stew into pieces suitable for the size of the cauldron. Various herbs were thrown in along with the meat, and perhaps some spices to give a zest; and after all was thoroughly cooked, those members of the family who were left partook heartily of the broth.

In doing this they had two objects in view, nay, three; they showed due respect to their ancestor, they imbibed his many virtues, and they got a passable meal.

On seeing one of these cemeteries this story almost invariably occurs to our mind, for although the Scythians took a rather direct way of discussing their relative, yet our present villagers also get the strained virtues and vices of their departed townpeople, in the water that seeps through the graveyard soil, trickles down the shelving strata, and at last finds its way into the wells and to the tables of the innocently anthropophagous villagers.

Annotations.

OKLAHOMA.

THE ancient game of "pussy wants a corner" has just been played in Oklahoma, but instead of finding the "corners" filled by laughing children, the unlucky late comer finds his desired homestead occupied by a burly citizen, armed to the teeth. For a moment the laws of civilized society, which aim at equalizing the rights of property, so that the feeble in body shall be as secure as the strong, have been suspended; and stalwart manhood again approves itself as the fittest to survive.

The eagerness with which the tract opened up for settlement has been taken, may attract public attention to the fact that good land for homesteads is becoming scarce. For many years the railroads and other land grabbers have cut and sliced away at the public domain as if it were indeed illimitable. Thousands of yonng men are trifling their lives away in the cities at occupations which offer no opportunities for advancement, while the lands that are their birthright are being taken by the German and the Swede. To many of that lower species of youth who work not, but take pride in the title of "tough," the influence of the pioneer life in developing true manhood would be far and away beyond the value of the homesteads they could still have for the asking.

DISSECTION WOUNDS.

APROPOS of a recent death in England from blood poisoning contracted by holding a post-mortem examination, the *Press and Circular* remarks that many such deaths recorded could have been avoided by the use of a little prophylaxis, and that they are probably due to the fact that familiarity in their cases, as in many others, is apt to breed a dan-

gerous contempt. A student in the dissecting room is greatly alarmed at his first scratch, he treats it with the best known preventive measures, and watches anxiously during several days for the classical symptoms marking the onset of a dissecting wound.

But as they do not appear he treats his next wound with somewhat less care, and both his alarm and attentions progressively decrease, till he finally begins to consider himself, for some unexplainable reason, invulnerable, and totally disregards a puncture from his tenaculum or a scratch with his knife. This is the experience of most students, and most students escape. Every now and then, however, the poison takes effect in some heretofore invulnerable student, and he may lose through his carelessness his hand, his arm, or his life. The same may be said of those who perform many post mortems. The *Press and Circular* remarks that the hands should be well anointed with vaseline before beginning, and that after the work is completed, they should be washed with a hot 20 per cent. solution of carbolic acid, or a 1–1000 solution of corrosive sublimate, and that a layer of collodion should be put over any abrasion of the fingers or about the nails.

RIGHT-SIDED APHASIA IN A LEFT-HANDED PERSON.

H. C. WOOD, M.D. (*Medical News*) says this case has seemed to him worthy of being recorded on account of the curious relations between the habitual use of the hands and the speech function. The aphasia was the result of a lesion in the left side of the brain. Although the person was for the ordinary purposes of life left-handed, he had always written with the right hand; the centres connected with writing, in locating themselves, so to speak, had followed not the centres of habitual physical action, but the centres of speech function. In other words, this man possessed a brain in which the speech centres were highly developed in the left hemisphere, although the motor centres for the hand and leg, and probably for the face, were more highly developed in the right than in the left hemisphere, and in which, when the art of writing was learned, the motor centres of the left hemisphere underwent special development, apparently on account of their close relations with the centres of speech.

PASSIVE RESPIRATORY MOVEMENT.

MASSAGE is growing to be a common affair, and many people take their muscular exercise quietly in bed, at the hands of some muscular masseur. It would seem that the time may not be far distant when certain of our race will have their breathing done by steam, for part of the day at least.

Dr. H. S. Taylor (New York *Medical Record*) writes a paper to prove the therapeutic value of systematic passive respiratory movements in those whose breathing capacity is abnormally small. The movements are much like those used in the Sylvester method of resuscitation; but the necessary exertion is relegated to a steam-engine. By appropriate machinery the arms are drawn up, and from thirteen to sixteen movements made in a minute. Dr. Taylor shows by tables that the breathing capacity is augmented, the chest measure increased, and the patient's general health improved.

TO AVOID OVERCROWDING.

IN the *Journal of the American Medical Association*, Boyd Cornick discusses the overcrowing of the profession. His remedy is not the passage of restrictive laws, which have proved "conspicuously futile," but the adoption of Henry George's system of land taxation. From this he promises us that a new difficulty will arise; that of providing means "to induce men of latent energy to devote the years of time and labor needed to qualify them for the laborious and responsible professions of law and medicine."

ELECTRIC DOOR-OPENERS FOR USE IN ASYLUMS.

THIS is the title of an article in the April number of the *American Journal of Insanity*, by Dr. M. J. White, Superintendent, Milwaukee Hospital for the Insane. In view of the fact that a number of sad catastrophies have happened in our country, in which helpless inmates caged in their rooms have been burnt to death along with the burning building, this topic is one which ought to engage earnest attention. The insane have an anomalous position or condition. They are not condemned criminals who are rightly incarcerated by force, nor yet, again, are they normal human beings who may go where they list. Their position is between. The safety of others demands that their freedom be denied them, yet for their own welfare it is important that the semblance of freedom be granted to them, and the best results are obtained, *cæteris paribus*, where the nicest balance is kept between these two points.

Many of the insane are rational on all but one or two subjects; their mental faculties are good, and their sensibilities acute. There is no reason why these patients, upon being locked in a room, and dependent for exit upon an attendant, should have sensations of less discomfort than we should have, were we to be fastened for the night in a stout room at a hotel, with barred windows, and the key of our door in the pocket of some servant who was sleeping three pairs of stairs distant, What would be our chances in case of fire?

These considerations must of necessity alarm patients, and we know for a certainty that they do alarm patients. Influenced by these considerations, Dr. White made a number of experiments in order to discover, if possible, some means of opening the doors simultaneously, either from the attendant's room or from his own.

As the machinery used in jails for this purpose would be unsuited to an asylum, being entirely too suggestive of force, he attempted to solve the problem with electricity, and succeeded. It is not our purpose to enter here into the details; suffice it to say that he succeeded in discovering a method by which the different doors could be simultaneously unlocked,

thrown open, and held open, by simply touching a button, either in the attendants' rooms of the various corridors or in his office. As we said at first, this subject merits the attention of all those who are concerned in these asylums for our unfortunate fellowmen, and we hope that it will not be long ere the system is in general use.

Letters to the Editor.

A CASE OF CROUP.

THE family of Mr. R., had lost three children, two boys and one girl, within the last two years. Therefore, when this little boy four years of age, their only child, was taken with unmistakable symptoms of croup, they lost no time in calling on me. I lived across the street, and that fact saved the child's life.

The attack came on in an acute catarrhal form, and as soon as the characteristic symptoms of true croup were manifested I began a treatment which I recommend as the very best. To prevent fibrinous exudation I gave quinine in large doses, four grains every three hours, and in connection with the quinine I gave bromide of ammonium also in large doses.

My next and most important effort was the use of lime spray as a solvent, and I used it in earnest; for my object was to keep the air of the room completely saturated with steam from slacked lime.

This was kept up till after the child could breathe freely. I used as an emetic subsulphate of mercury when breathing was too much obstructed, and at three different times large pieces of false membrane were expelled by the use of this emetic. The child became very much worse on the fifth day, and stimulants were freely given. Knowing the crisis would come on about the seventh day, I stayed with the patient day and night. To get a closer application of the lime vapor I made a large funnel and had the child breathe directly from the funnel, the large end having been placed over slacking lime. About 4 o'clock on the seventh morning the patient appeared to be dying, the pallor of death came over the face; the eyes even set, the pulse was imperceptible at the wrist, and the bowels acted involuntarily. I gave hypodermic injections of brandy and rubbed well the body with warm water and whisky; and soon had the satisfaction of seeing signs of returning life in the child, which made a complete recovery from that time.

I know that the above case was true croup in its worst form, and must give the lime the credit of dissolving the membrane as it formed, therefore preventing death from asphyxia. I have since treated four cases successfully with the same treatment, and don't think the treatment can be beaten.

J. D. KELLEY, M.D.

SEVERY, KANSAS.

TYPHOID FEVER COMPLICATED WITH DYSENTERY.

J. M., about forty years of age, came to my office for treatment. He said that he had been at work on a canal boat, and had been unable to work for some days, having been confined to his bed. He said he was having twenty-four actions of the bowels a day. On his way to see me he had an intestinal hemorrhage, and he was so weak that it was with great difficulty that he reached my office. After having him taken to suitable quarters I began active treatment. Magnesiæ sulph. was given, followed in a few hours by the tinctures of Kino and camphorated opium. This combination, generally so good, acted in this case little better than so much aqua pura. All the drugs which I used to check the dysenteric discharges were of no avail, until I used a combination of opium and plumbi acet., which acted like a charm. By using that I kept the stools down to about four per diem. The first week I had but little hopes of him, not on account of high temperature, because the mercury never reached much above 103°F., and I did not have to use antipyretics. There was considerable insomnia, which was relieved by opium at bed time. He was well fed throughout his sickness, and the benefits accruing from this and the pil. opii et plumbi acet. are points which I will emphasize. When he first came for treatment he had a dicrotic pulse and was very weak. Supporting treatment was immediately adopted, and he had administered to him regularly one raw egg and a tablespoonful of whisky every two hours. At bed time he had milk placed near his bed within easy reach, so that he could partake of it during the night. He was not delirious in the least during the whole course of his illness. If those who are well require food, how necessary is it that individuals suffering from typhoid fever, acute mania and other exhausting diseases should be given the most concentrated as well as the most nourishing food (adapted to the case) that can be obtained. The question of feeding in this class of diseases, is happily a matter which in the present age is attracting almost universal attention. My patient in time fully regained his health and strength.

The Inquirer.

DID SHE PASS IT?

KATE D., aged forty-four, married, applied for treatment, saying, she had worms. Upon being questioned she replied her symptoms were swelling of the stomach, terrible boring of the nose, grinding of the teeth, etc. To confirm her diagnosis she brought in a bottle a worm of the following description, which she declares passed her rectum: It was about one and one-fourth inches long, with alternating stripes encircling the body of light yellow and dark brown color. At the upper portion of the body were six distinct feet or legs, with none at the other end of the body which ended in slight yet distinct bifurcation. She says it lived about ten hours after being passed, and that she experienced much pain a day or two before passing it.

She was given santonine and calomel for two days, when she returned, saying she passed a great deal of slime but no worms, and that she felt very much better. She was then told to wait a few days without any medicine and see if she had any return of the

symptoms. In three or four days she again returned, saying she was troubled just as before. The calomel and santonine was again ordered for two days, when she returned with a bottle containing three large round worms, about six or eight inches long tapering at both ends as the result of treatment. Said she felt much better, only a little weak. She was then put on a tonic, with instructions to return if not entirely cured. J. R. W.

REPRESSION OF MENSTRUATION.

I WOULD like to know if there are any remedies that will stop menstruation in a delicate female.

I have had two girls recover in whom nature suspended the flow for a year. They grew stout. I could only *relieve* them before this occurred. There is a class of debilitated people who can't spare the flow, and are sick every time it comes.

JNO. A. ELLIOTT.

NORTHUMBERLAND, PA,

[Gehrung recommends packing the vagina with balls of absorbent cotton, squeezed out of a 1 to 2 per cent. alum solution. Lœwenthal used hot water to the vagina. Several authors have spoken favorably of this idea.]

ADVICE WANTED.

I HAVE had great pain constantly in the region of my liver and in my bowels, with a continued severe soreness in the stomach, to the touch, or on the least jar, for more than two years. The bowels are costive. One minute's exertion completely exhausts my strength. I have always been a stout, healthy man, not having had one hour's real sickness in twenty years. I am sixty-eight years of age. I am *astonishingly weak*. My skin is reasonably moist and I have a fairly good appetite. I have no recollection of seeing a similar case mentioned in the books when I studied medicine. Perhaps you can kindly suggest something. WM. KISKADDIN, M.D.

DENVER, COL.

[We would recommend rectal injections of a pint of hot water every four hours; with hot applications to the abdomen and a diet of milk exclusively. The condition may be simply due to constipation with ulceration of the bowels. At any rate, there is nothing in the history as given above to indicate the disease more definitely, or to call for any other treatment. Perhaps, in view of the weakness, the best application to the abdomen would be an inunction of hot cod-liver oil.]

CACTUS GRANDIFLORA.

I SEE by the issue for March 9, 1889, that Dr. Mickle, of Baltimore, claims that cactus grandiflora was introduced by Dr. Rubini, of Naples, and refers to the *Medical Record* of September, 1868. I do not know who originally introduced the remedy, but in 1865, Dr. Lippe, a homœopath, published a monograph on cactus grandiflora in heart disease. Also, in the *Eclectic Medical Journal* for December, 1866, p. 573, Dr. John M. Scudder tells what he knows of cactus after using it during the two years past. He refers its introduction to the homœopaths. I learned its use of a brother practitioner more than fifteen years ago, but cannot say where he learned its use. I have never used it in any other than chronic heart disease, though I cannot see why it might not be useful in acute diseases in which we have a weak heart and rapid and irregular pulse. I have found it a remedy acting slowly, and one that must be administered a long time. Get a good preparation, give it a thorough trial, and you will not wish to be without it. C. L. GREGORY, M.D.

YREKA, CAL., March 19, 1889.

AN OBSTINATE CASE OF ECZEMA.

I HAVE in charge an obstinate case of general eczema, but especially in the legs, where the tissue is markedly infiltrated, from slightly above the knees to the toes. With the exception of the legs, the remainder of the body has partially yielded to treatment; but the itching, burning, and smarting in his legs almost drives him crazy. The case is complicated by prostatic trouble, the patient's age being seventy years. I have used many lotions, containing the following, at different times: Sodii bicarb. hydrocyanic acid, calamine, oxide of zinc, with starch, cocaine, gindelia robusta, ol. cadii, plumbi subacet., dilute hydrocyanic acid, and other things; but finally used carbolic acid. This answers very nicely by applying it every few hours, say about one drachm to three pints, and sponging the surface all over, and afterwards applying roller bandages of cheese cloth saturated with the same solution. The smarting and burning now is largely from the skin, as the infiltration has been removed with the exception of that of one leg. I have given internally potassium iodide, arsenic, elix. iodo-brom. calc. comp., elix. ferri et strych., and now have him on tinct. iron and quinine. I have to give him chloral at night. Any suggestion would be gratefully received.

M. FURLONG, M.D.

[We would suggest the following course of treatment outlined by Shoemaker in his work upon "Diseases of the Skin," published by Appleton & Co., New York, and would refer the doctor to the above volume, which gives all the recent views and a rich clinical experience upon eczema. Rest is essential for even relief in obstinate cases of eczema involving the legs. The patient should be put in bed, or if allowed to move around, the limbs should be bandaged. A hot alkaline bath two or three times a week will be of advantage.

The following ointment may be employed with benefit (from Shoemaker's Formulary for Diseases of the Skin, page 586):

Take of Oil of cade	30 drops.
Sulblimed sulphur	1 scruple.
Ointment of oxide of zinc . .	½ ounce.
Cerate of subacetate of lead,	½ ounce.—M.

Internally, give a half a drachm of the fluid extract of hamamelis alone, or with glycerin, three times a day. The action of witch-hazel is also explained at length by the above author in eczema of the legs.—EDITOR]

Society Notes.

ALLEGHENY COUNTY MEDICAL SOCIETY.

SPECIAL MEETING MARCH 19, 1889.

WILLIAM F. KNOX, M.D., President, in the chair.

DR. DUFF reported a case of rheumatism accompanied by a rash at first papular then vesicular, the rash following the joints as they were affected. After the rash left the cervical and submaxillary glands enlarged and suppurated, after which the patient rapidly improved.

DR. PAINTER exhibited a woman of forty, with a congenital malformation of the palate. The palato-pharyngeus muscle of either side along with the free border of the soft palate are carried backward and attached to the posterior wall of the pharynx, forming a sort of diaphragm between the upper and the lower portions of the pharynx. Through this diaphragm in the median line are two openings—one one-half and the other one-eighth of an inch in diameter. Her senses are all good, save her voice which is slightly muffled.

DR. HUSELTON reported a case of compound punctured fracture of the skull, produced by the calk of a horse's shoe.

After the kick the patient was unconscious for about an hour, but not afterwards. Examination revealed a depressed punctured fracture of the skull, situated two inches above the right eye. The fracture was about the size of an almond, and from the wound there constantly oozed a sero-sanguinolent fluid, but after trephining no break in the dura mater could be found. He was discharged in twenty days after admission to the hospital, the opening in the skull apparently filling up by bony deposit.

DR. BUCHANAN thought that trephining was not only eminently proper in the case related, but that it is in accord with our present knowledge of the secondary results of depressed fractures, at least an exploratory incision through the scalp would often be justifiable, where nothing is now done, to see if any depression could be found.

DR. MUNN related a case illustrative of Dr. Buchanan's remarks. A depressed fracture was found on the skull of a man who had been thrown from a carriage, but the family would not hear to an operation. He then went under homœopathic treatment, and recovered after having been unconscious seven days. After eleven months he has double vision, slight paralysis of right arm and leg, some aphasia, and has had two epileptic seizures, though he never had anything of the kind before.

DR. BUCHANAN exhibited a patient with perfect recovery, whose patella he had wired some months previously.

DR. MURDOCH admitted that the patella felt as if there were bony union, but doubted if such union ever took place. He also considered the operation exceedingly dangerous, citing a number of cases that afterwards suffered amputation and finally died. He considered the plan of tieing the fragments together, subcutaneously the best method that had yet been suggested.

DR. HUSELTON thought wiring a broken patella would never become a popular operation. It was too dangerous.

DR. BUCHANAN admitted that subcutaneous tieing was much safer, but thought there were two great difficulties connected with it: accurately approximating the fragments as to their edges, and also keeping from between fragments of the torn capsule.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

STATED MEETING APRIL 10, 1889.

W. W. KEEN, M.D., President, in the chair.

(Abstract of Proceedings.)

DR. G. E. SHOEMAKER read a paper on Early Recognition and Treatment of Malignant Disease of the Uterus, in which he laid stress on the importance of such early recognition, as that is the time when the neoplasm can be most easily removed, and with the most favorable prognosis; but it is just at this time that the "average practitioner is at fault. Perhaps through lack of confidence in his own powers of diagnosis, perhaps from a general impression that no benefit would be derived from treatment, perhaps from a personal distaste for such examinations and long disuse of them except before and during labor; from whatever cause it may be, cases of malignant disease of the uterus are too often allowed to drift along through a most important period unrecognized. Even if not a specialist, if a practitioner will take the trouble to do his very best he can learn much in such cases. Let him take plenty of time, go to the trouble of securing a good light so that he can see clearly, let him see the case on his office chair if possible, at any rate not with the hips half buried in a bed, placed as far as possible from a heavily curtained window."

Among the early symptoms are: more or less bleeding, evidence of impaired vitality and loss of tone, pain, though in some cases this symptom is remarkably absent. In order of frequency malignant growths of the uterus are as follows: epithelioma, encephaloid cancer, sarcoma, scirrhus cancer.

In epithelioma the finger finds the cervix harder than usual, nodules are seen in cervical canal of pale, yellow or red color.

The early diagnosis of encephaloid cancer is rarely, if ever, made. The usual point of origin is near the lower end of the cervical canal, in the submucous tissue.

The accurate diagnosis of sarcoma of the uterus is rarely possible, either early or late, without a microscopical examination of a section large enough to show not only characteristic cells, but their relations to surrounding tissue. It occurs in two forms, *circumscribed* and *diffuse*.

Treatment "is of course, eminently surgical. As in cancer of the breast, not every case of malignant tumor of the uterus is to be operated upon by any means. There is room for the exercise of much judgment. One fact, however, is established beyond all question, it is that years of life and great suffering may be saved by early and radical removal, especially

of epitheliomas. If the operation is not thorough, life is shortened by it, except in the later stages."

With regard to a partial operation or complete extirpation of the uterus for malignant disease, the history of one hundred and twenty-nine cases operated on at the University Frauenklinik, Berlin, are interesting:

At the end of the first year 51 per cent. of the partial cases remained well.
" " second " 46 " " " " " "
" " thi d " 42 " " " " " "
" " fourth " 41.3 " " " " " "

Again, at the

end of the first year, 63.6 per cent. of the complete cases remained well.
" " second " 24.1 " " " " " "
" " third " 26 " " " " " "
" " fourth " *not one living* complete case remained

Summary:

a. Early diagnosis is all-important, and should not be deferred until gross changes have occurred.

b. Examination should follow slight suspicions from the treacherous character of the symptoms. If not conclusive, it should be made by a trained hand.

c. The microscope will sometimes detect before other means will.

d. Heredity is a doubtful cause, traumatic origin very probable.

e. Lacerations of the cervix, where the growths usually begin, should be repaired if causing irritation, and erosions should be cured. If erosions are stubborn, or otherwise suspicious, they should be pared off.

f. In epithelioma especially, the disease is at first local, and if taken early complete immunity is secured sometimes, and always great saving of time and suffering.

g. From an operative point of view there are three periods in any form of malignant disease.

1. Early, when operation should be immediate and as radical as possible, without extirpation of the uterus.

2. Intermediate when, eradication being impossible, nothing should be done unless demanded by severe hemorrhage or extreme pain. The length of this period is indefinite, and depends on the rapidity of growth.

3. Late, when scraping and burning may be done repeatedly, to palliate symptoms and retard growth.

EXTRA-UTERINE PREGNANCY — OPERATION — RECOVERY.

Dr. E. P. Bernardy read an account of a case in his practice that exhibited all the classical symptoms of a ruptured tubal pregnancy. The case was operated on by Dr. Joseph Price, whilst there were present: Prof. Agnew, Drs. Levis, M. Price, Kynett, E. P. Bernardy. The usual incision was made, and the abdominal cavity opened. Ruptured left tubal pregnancy. The left appendages filled the pelvic basin, the primary rupture having occurred between the folds of the broad ligament, with secondary rupture into the peritoneal cavity. General firm adhesions. The pelvis was emptied of clot, the placenta and membranes coming away in the tube, the right tube was diseased; hydrosalpinx; it was removed. Irrigation and glass drainage. The patient is now entirely well; with the exception of a somewhat prolonged shock following the operation there was no bad symptom.

This case was discussed by Drs. Hoffman, Bernardy, G. G. Davis, J. Price, and J. M. Baldy.

Book Reviews.

Report of the Superintendent of Public Instruction. By the State Superintendent for Pennsylvania, E. E. Higbee

This report fills some 400 pages in a well bound volume from the hands of the State Printer.

Mercks Index of Fine Chemicals and Drugs for the Materia Medica and the Arts. "Comprising a summary af whatever chemical products are to-day adjudged as being useful in either medicine or technology. A guide for the physician, apothecary, chemist, and dealer." By E. Merck. First American edition. Price, $1.00,

---

Ninth Annual Report of the Illinois State Board of Health, with an appendix embracing Report on the State Sanitary Survey, Vital Statistics of Illinois and Coroners' Inquests, Meteoralogical Tables, Report on State Medicine in 1886; the whole embraced in a paper bound volume af some 300 pages.

1889 is a rather late date for a report of the year 1886, but a note explains that the delay was due to some complications in the State printing contract.

International Pocket Medical Formulary. By C. Sumner Wilkerstine, M.S., M.D. F. A. Davis, Publisher. 1888: Philadelphia and London. Price, $2.00.

This is a neat and compact little volume, containing a large amount of information in a small compass. The formulas are taken from the best known men, both here and abroad, and are so indexed that a desired one may be found in an instant. Many a busy practitioner who has not always time to consult his larger works will, we think, find this compendium of value. In the appendix is a posological table, formulæ for hypodermic medication, formulæ of medicines for inhalation, and much other timely matter.

The Psychic Life of Micro-Organisms. A Study in Experimental Phychology. By Alfred Binet. Translated from the French by Thomas McCormack, with a preface by the author, written especially for the American edition. Chicago: The Open Court Publishing Company, 1889. Price, 75 cents.

The wonderful revelations of Metschnikoff awakened an interest in the life of micro-organisms, one of the results of which is the volume before us. It will be found a bit of very interesting reading; and to one who is not familiar with recent investigations upon the subject treated, a new and attractiue field will be opened up. The more closely one studies the nature and habits of animals the more indistinct becomes the boundary between instinct and reason. In his studies of protoplasmic psychology, Binet has progressed farther on this path than one would think possible to go, until he has read this book.

Abstracts.

LABOULBENE says that the tears contain the contagious agent of measles, and that inoculation with them always produces a mild type of that disease.

MÉNIÈRE (*Gaz. de Gyn.*) disposes of the homœopathic claim for priority in the use of hamamelis, by citing Collinson, "Dictionaire de Mérat et Deleus," 1736, twenty years previous to Hahnemann's birth. Even if the little men had been the first to suggest the employment of the remedy, the credit must be given to him who discovers the dose capable of producing therapeutic effects.

ABORTIVE TREATMENT OF GONORRHŒA.—Dr. Rively treats recent cases of gonorrhœa by direct application of balsam copaiba to the urethra. He puts it on a bougie and passes it in the urethra. After the first application of the bougie, which should be left in situ for six to eight minutes, the discharge disappears. But to be sure the treatment should be continued for some days. There is very little pain under this treatment.—*Wiener Medizinische Presse.*

TREATMENT OF LEG ULCERS.—Dr. Appenrodh, of Clanthal, introduces a new method of treatment for ulcers of the leg. After washing the leg he uses mild massage, beginning at the knee and working downwards, which produces an exudation of lymph in the ulcer, and a cure rapidly results. Pure lanolin is recommended as a dressing in preference to that charged with antiseptics which ordinarily produce irritation.—*L'Année Médicale.*

THE DEATH-CURRENT.—In the *Medico-Legal Journal* for March, is an account of several interesting experiments with regard to the strength of current necessary for instant death. The experiments were made by Mr. Harold P. Brown at the request of the committee appointed to determine the best means of putting into effect New York's present law of execution. It was found that an alternating current of 700 volts was instant death to the calves and horses experimented on.

ELECTRICAL CATAPHORESIS AS A THERAPEUTIC MEASURE.—Frederick Peterson, M.D. (New York *Med. Journ.*), gives a series of experiments to prove that by the use of a galvanic current anæsthetic medicaments, cocaine, aconite, and the like, can, by osmotic action, be passed through the unbroken cuticle into the subjacent tissues. For instance, in neuralgias he applies to the affected part the anode sponge saturated with a 10 to 20 per cent. solution cocaine, the current is completed by putting the cathode on any convenient part of the body; and after the passage of a current ranging from five to seven milliampères for from four to ten minutes, marked anæsthesia appeared and relief from pain, the latter lasting in one case as long as eleven hours after the application. Check experiments were made both with cocaine alone and with electricity alone, in both cases with no effect.

LEMON SANTAL ESSENZ IN THE TREATMENT OF THE DISEASES OF THE URINARY ORGANS.—Dr. Delattre calls attention to lemon santal essenz, administered in capsules of three-grain doses three or four times a day in diseases of the urethra, bladder and kidneys, and the good results which he obtained by its use.

He mentions a case of chronic blenorrhœa, where copaiba and cubebs were given without lessening the discharges; but after the administration of lemon sandal for three days the discharges lessened considerably.

In a case of stubborn gonorrhœa with greenish thick discharge and a constant desire to urinate, eight capsules of the lemon sandal taken in twenty-four hours, relieved the constant desire to urinate and urination became painless; the discharge was soon stopped.

A third case was of pyo-nephrosis of eighteen months duration, which obliged the patient to stop work, to rise several times each night to pass his urine, which was mixed with pus.

He gave four sandal capsules mornings and nights; the pus in the urine diminished at once, and the urine became clear. Two weeks afterwards the patient's health was regained, and he was able to take up his usual work.

Five cases of cystitis were cured in from two to three days.

Stricture of the urethra, with hypertrophy of the prostate and catarrh of the bladder, where the bougie had to be used, were cured in a few days by the administration of lemon sandal capsules.

In a case of nephritic colic, where chloroform and hypodermatic injections of morphine and baths did no good, he ordered three sandal capsules the first day. The patient passed a quantity of reddish urine with plenty of gravel, and slept all night, something he had not done since the commencement of the disease.

He cites a case of albuminuria, due to scarlet fever in a girl twelve years old. The urine contained large quantities of albumen, and dropsy was also present. He gave sandal capsules without much hope of success. After eight days the dropsy had disappeared and the urine became normal.—*Wiener Medizinische Prssse.*

METALLO-THERAPY IN HYSTERIC CHOREA.—(*La France Mèd.*), Mericourt reports a curious case of hysteric chorea. The patient was fifty years old, and her disease dated from the death of a child, five years previously. She was anemic, had defective hearing and vision, and was subject to neuralgia. Her digestion was feeble; menstruation had been absent for many months, and she frequently suffered with pains and burning in the temples and the vertex, while her feet were cold. Twice she had had epistaxis which necessitated the tampon.

The nervous crises, which often followed opposition, occurred generally between 2 and 5 A.M. Often they were replaced by insommia.

They commenced with a feeling of sadness, a desire to weep; sometimes with headache, anorexia,

nausea or diarrhœa. Then follows shivering in all the members and an imperious impulse to walk, cry, sing, and to kiss everybody. When time permits, she promenades with her husband for many hours in the fields.

These crises last about five hours, and occur on the average two or three times a month; often many times in a week, rarely being absent for three months.

Pronounced anæsthesia and analgesia were found on the external surface of both forearms.

Upon each forearm was applied an armature composed of four discs of steel. In ten minutes she felt in the right arm a gentle warmth which passed shortly to the left arm, oscillated between the two and then disappeared. The skin then proved somewhat more sensitive, but the muscular force fell two kilos on each side.

Next day, two armatures of copper having been applied in the same manner, the patient experienced a sensation of pain and of warmth, more decidedly than after the steel. The analgesia was diminished, the anæsthesia increased, and the muscular force was unaltered. But during the whole day the patient had pains at intervals in the forearms.

Zinc, tin, gold, silver, aluminium were tried successively, without result. She was sensitive then only to copper, and in a less degree to steel

Desiring to avail himself of this double sensibility, he prescribed eau d'Orezza, and external applications of copper. The appetite returned and the crises ceased. Twelve days from the beginning of treatment menstruation reappeared.

The treatment was continued for over two years, with some intermissions, during which the crises showed a tendency to reappear. The menopause was definitely established, and for eight months no crises had occurred, though the flushes still annoyed her, especially after eating. She still took copper internally.

THE DANGER OF CHLOROFORM BY GASLIGHT.—Several observers report a peculiar gas, formed in the the room, where chloroform is administered.

It is thick and looks as if a fog were diffusing in the whole room, and smells like chlorine gas.

Prof. Iterson-Leiden reports several severe and unexpected asphyxias during chloroform narcosis, and even one death, which took place very suddenly after the operation was completed. The patient was conscious and had spoken, when suddenly she became cyanotic and ceased breathing. All efforts at resuscitation were fruitless.

After this the room was warmed by a stove, the lighting of the gas dispensed with, and he had no more abnormal chloroform narcoses or asphyxias.

Dr. Fischer, during long operations, where chloroform narcosis lasts over a half hour, and gas has to be lit, notices that all present, physicians as well as nurses, begin to cough, and the irritation becomes stronger the longer they remain in the room; afterwards come headache, vertigo, a feeling of apprehension, sickness of the stomach, and even vomiting in some cases. All these symptoms disappear upon going into fresh air.

The secretion of the nose and the sputa were increased and mixed with black dust particles. The evolution of the gas is not due to a bad construction of the gas lamps, for these symptoms were never recognized in the room where no chloroform was administered.—*Berliner Klin. Wochenschrift*, April 1.

TREATMENT OF POTTS' PARALYSIS BY SUSPENSION.—S. Weir Mitchell, M.D. (*Am. Jour. Med. Sciences*), has found that he gets much better results in this disease by treating it with suspension, after the plan followed by his father, than he can by the modern plan of rest, tonics, and cauterization. He cites several of his own patients on whom all the ordinary therapeutic measures were tried without avail, who steadily went downward till they were completely paraplegic with all the concomitants. He then tried suspension, with most marked, and, in one case especially, we may say, brilliant results.

His father used but a small amount of traction, and that cautiously, but Dr. Mitchell determines the amount of traction to be used by the feelings of the patient; it may be twenty, seventy, or a hundred pounds, for from one to four hours twice a day, or sometimes it may be the entire weight of the patient's body. The apparatus is much like that attached to the head when putting on a plaster jacket, and it may be fastened to the bed or a chair.

Dr. Mitchell's conclusions are as follows:

That suspension should be used early in Pott's disease.

That used with care, it enables us slowly to lessen the curve.

That in these cases there must be in some form a replacement of the crumbled tissues.

That unless there is great loss of power, the use of the spine-car or chair, etc., of John K. Mitchell, enables suspension, especially in children, to be combined with some exercise.

That no case of Pott's paralysis ought to be considered desperate without its trial.

That suspension has succeeded after failures of other accepted methods.

That the pull probably acts more or less directly on the cord itself, *and that the gain is not explicable merely by obvious effects on the angular bony curve.*

That the now well-known influence of extension in Pott's palsy makes it probable that in other forms of spinal disease, not due to caries, extension in various forms may be of value, as has apparently been of late made clear.

That the methods of extension to be used in these and in carious cases may be very various, only provided we get active extension.

That the plan and the length of time of extension must be made to conform to the needs, endurance, and sensation of the individual cases.

SALOL IN DISEASES OF THE UTERUS.—Dr. Vuillet uses salol in the form of cotton tampons in diseases of the uterus as an antiseptic dressing. Drs. Creyx and Jarry use equal parts of salol and amylum as a dusting powder in fungous granulation of the uterus and in vaginitis.—*Journ. de Pharm. et de Chirurgie.*

Medical News and Miscellany.

MINERSVILLE has the mumps badly.

ALLENTOWN still suffers with diphtheria.

DR. R. G. STRETCH has removed to No. 1823 North Eighteenth Street.

FUMIGATION with sulphur is a new Chicago idea for the preservation of food.

AN Italian in Jersey City is said to have lived a week after a pistol ball had passed through his heart.

"GOLDEN TINCTURE" is composed of one part chloroform and four each of ether, laudanum, and alcohol.

THE Medical profession carries on its work, not for the benefit of the medical profession but for that of humanity.—*Plato.*

F. J. THORNBURY, M.D., a graduate of the Ohio Medical College, has been appointed interne at the Cincinnati Hospital.

THE bill appropriating $5,000 to the Medico Chirurgical Hospital of Philadelphia, has received Governor Beaver's signature and is now a law.

PARISIAN diabetics can now obtain palatable bread, made from the embryos of wheat, and containing abundance of nitrogen, but no starch.

DR. ECCLES (*Drug. Circ.*) is after the Paris Medicine Company, and shows that their febriline, claimed to be tasteless quinine, is simply quinidia.

AMBROSIA has been up before the Courts, and has been authoritatively pronounced to be a weak beer, with an alcoholic strength of 1 to 2 per cent.

THE *Lancet* says that within the last few years many persons have been murdered by poison, the motive being the sum obtained from insurance societies or burial clubs.

STEAMING has been shown to be an efficacious method of destroying the germs of yellow fever. Ten minutes' exposure proves to be sufficient to render them harmless.—Syracuse *Standard.*

THE sense of pressure is generally greatest in the same localities at which the sense of touch is most developed, the skin of the forehead, temples, back of hands, and forearm distinguishing a weight of $\frac{3}{100}$ grain.

A GENTLEMAN fell dead during sexual intercourse. Ten months from that day his widow gave birth to a child. She was a very respectable person; one not likely to throw herself away under such awful circumstances.

TYPHOID still creeps along through Luzerne county. This is inexcusable. With proper disinfection of the stools, typhoid should stop with the first case in country places. In the city it is more difficult, as the sewers offer avenues for the spread of contagion; but much good will ensue if every physician does his duty with the cases in his charge.

AGASSIZ, on being urged to leave his work to deliver a lecture, was told, as an inducement, that he would realize a large sum of money by doing so, but the great man replied, "I have no time to make money."

THE papers upon surgery in the editorial columns of the *Medical News*, embodying the results of extended researches in the space of a page, were the work of the late S. W. Gross, whose place in that respect it will not be easy to fill.

THE time of year has arrived when the patent medicine men are soaking the labels off their bottles of "cough mixtures," "sure cure for coughs and colds," and substituting bright new ones of "sure cure for diarrhœa."—*Kansas Med. Journal.*

MINER'S MILLS has a visitation of typhoid fever. Instead of giving us disquisitions on the nature of typhoid fever why don't our country members put on record the facts concerning these outbreaks of typhoid in isolated places. Whence come they?

RECENT statistics from Germany are of interest. This is the only country in which revaccination is compulsory, and the death rate from small-pox is so low that all other civilized countries are far away behind. The deaths from vaccination averaged one per million.

THE St. Louis *Globe-Democrat* says that over 45,000 surgeons are connected with the railroads of this country. Too many! We have only been able to find 86,409 physicians, of all schools and no schools, in the United States, including Canada, to whom the DIETETIC GAZETTE is sent. We cannot believe that over one-half the physicians are railroad surgeons.

YELLOW FEVER has appeared at Callao, Peru. This is bad news for our navy, as the west coast has been long a desirable station, because neither cholera nor yellow fever have visited it. The Cape of Good Hope is another favored spot in regard to this disease, though the visitor there has still a very fair chance of ophthalmia and rheumatism, and a slight one of the leprosy.

AMONG the causes of death reported in Philadelphia last week were the following:

Cerebro-spinal-meningitis, 2; cholera infantum, 2; consumption of the lungs, 50; croup, 9; diphtheria, 7; erysipelas, 1; scarlet fever, 9; typhoid fever, 10; pneumonia, 35; measles, 5; purpura hemorrhagica, 1; septicæmia, 3; whooping cough, 5.

THE custom of wearing the pantaloons buttoned tightly at the top, and sustained by the hips, produced so much disease even among the hardy soldiers of the Russian army, that a law was enacted making the wearing of suspenders compulsory. If strong men suffer thus, how much greater must be the injury to frail, delicate women! The constant pressure and unnatural heat to which the lower part of the back is subjected, is one of the chief causes of the frequency of kidney diseases among women. Here is found the source of "weak back," lumbago, pain in the side, and several other diseases of the trunk which affect so many thousands of American women.—*Good Health.*

THE SANITARY NEWS thinks the time will come when the plumber will be employed as the family physician is, and have reposed in him the same confidence.

We hope most devoutly that the time will come when the plumber will deserve it. At present his ingenuity seems to be wholly expended in devising ways of not doing his work properly.

WHEN an impassable urethral stricture exists, and the surgeon, after performing external urethrotomy, is unable to find the urethral opening, supra-pubic tapping can be done, and the bladder catheterized from behind forwards. The sound is passed forwards to the stricture, another instrument passed from the front, and the intervening stricture-tissue incised.—*Med Press.*

SEVERAL years ago we witnessed an amusing scene in a coach on a railroad that had lately been built through a highly rustic part of Pennsylvania. There was a girl of some eighteen summers in the car, evidently for the first time in her life, who could not be prevailed on to take a seat, but persisted in standing in the middle of the aisle, lest by adding her weight to one or the other side the delicately balanced car might be overturned.

AMONG the names prominently mentioned for the vacancy created by the death of Prof. S. W. Gross, are those of Charles Parks, of Chicago, Hal. C. Wyman, of Detroit, Hunter Maguire, of Richmond, and Nicholas Senn, of Milwaukee.

Of our own local surgeons an acceptable choice could be made from among Drs. J. M. Barton, W. W. Keen, J. Ewing Mears, C. S. Nancrede, John B. Roberts and W. J. Hearn.

IN the latter stages of Bright's disease, much relief might be obtained from morphine, were it not for the alarming and even fatal results which sometimes follow its use. It is to be regretted that we cannot as yet specify the cases in which morphine is likely to do harm. As the ill effects are due to a failure of the kidneys to eliminate the drug, it might be thought that uræmia was the contra-indication. But as uræmia causes spasm of the arterieles, with headache, etc., morphine may relieve this by relaxing the spasm.—*Med. Press.*

THERE is trouble in the ranks of the Women's Temperance Hospital Association of Chicago. That institution, organized to ascertain how near its founders could come to curing people without the use of alcohol, has been supported by Dr. Mary Weeks Burnett, the talented editor of the *Journal of Heredity*, and her friends, who contributed lavishly towards its expenses. Now it appears that Dr. Frances E. Willard, the no less talented editor of the *Union Signal*, a medium for the dissemination of homœopathy under the guise of temperance, has walked in and taken possession of the Hospital, turning out the other party, bag and baggage. And this, notwithstanding the fact that Miss Willard not only contributed nothing towards the expenses of the hospital, but charged it $25 for a speech at its opening.

THE DOCTOR AT BAY.—This is the title of an article in the *Hospital Gazette*, April 20, written by one "John T. Biernaski, L.R.C.P., L.R.C.S.," etc. It begins by citing an article from the New York *Med. Cycle*, June 3, 1884, which is given as a prologue, but which we think is perhaps intended as a sort of key to the cryptogram following. The production is given in the form of scenes. How many of these there are to be we know not, but Scene I itself consumes three valuable columns, and our heart sank at noticing "*to be continued*" appended. So far as we could gather from a careful reading the article is intended to be funny, but although greatly desiring at that time to relax our features we could not conscientiously do so, feeling, on the contrary, like weeping at the thought that "John T. Biernacki, L.R.C.P., L.R.C.S," etc., should thus have missed his time. It may be, however, that we have been premature in our remarks, and that John T. Biernacki, L.R.C.P., L.R.C.S., etc., has a way of leading one up to the point and then at the end surfeiting the reader with facetiousness. We await the outcome with great interest.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 23, 1889, to May 6, 1889.

MAGRUDER, DAVID L., Colonel and Surgeon. The retirement from active service this date, by direction of the Secretary of War, by operation of law, under the provisions of the Act of Congress approved June 30, 1882, is announced. Par. 4, S. O. 94, A. G. O., April 23, 1889.

VALLUM, EDWARD P., Colonel and Surgeon. Promoted to Surgeon, with rank of Colonel, from April 23, 1889.

WRIGHT, JOSEPH P., Lieutenant-Colonel and Surgeon. Promoted to Surgeon, with rank of Lieutenant-Colonel, from April 23, 1889.

WOODRUFF, Major and Surgeon. Promoted to Surgeon, with rank of Major, from April 23, 1889.

FORWOOD, W. H., Surgeon. Leave of absence for one month, based on Surgeon's certificate of disability, with permission to leave the limits of the Department, is granted. Medical Department, Fort Snelling, Minn. Par. 1, S. O. 35, Headquarters Department of Dakota, St. Paul, Minn., April 8, 1889.

WOODRUFF, EZRA, Captain and Assistant-Surgeon. Is relieved from duty at Fort Missoula, Montana, by direction of the Secretary of War, and will report in person to the commanding officer, Fort Monroe, Va., for temporary duty at that port. Par. 14, S. O. 92, A. G. O., April 20, 1889.

WALKER, FREEMAN V., First Lieutenant and Assistant-Surgeon. Leave of absence for four months, by direction of the Secretary of War, on Surgeon's certificate of disability, with permission to leave the Department of Texas, is granted. Par. 12, S. O. 92, A. G. O., April 20, 1889.

BORDEN, WILLIAM C., Captain and Assistant-Surgeon. Relieved from duty at Fort Ringgold, Texas, and ordered to report to the commanding officer at San Antonio, Texas, for duty at that post. Par. 7, S. O. 100, A. G. O., May 1, 1889.

FISHER, WALTER W. R., Captain and Assistant-Surgeon. Leave of absence for one month is hereby granted. Par. 1, S. O. 30, Headquarters Department of California, San Francisco, Cal., April 27, 1889.

Changes of Stations of Medical Officers.

HOWARD, VALERY, Assistant-Surgeon. Relieved from duty at Fort A. Lincoln, Dak., and ordered to Fort Buford, Dak.

CRAMPTON, L. W., Assistant-Surgeon. Relieved from Fort Bridger, Wyo., and ordered to Fort Lyon, Cal.

SPENCNR, W. G., Assistant-Surgeon. Relieved from Fort Yates, Dak., and ordered to Fort Bridger, Wyo.

ROBERTSON, R. L., Assistant-Surgeon. Relieved from Fort Buford, Dak., and ordered to Fort A. Lincoln. Par. 29, S. O. 95, A. G. O., April 24, 1889.

Clinical Lectures.

HEMIPLEGIA.

BY WHARTON SINKLER, M.D.

(Delivered at the Philadelphia Hospital.)

(Reported by MANLEY F. GATES, M.D.)

AS hemiplegia is one of the affections which you will most frequently see, I think that it will be well to show you to-day some of the numerous cases which we have in this hospital.

When paralysis involves one lateral half of the body it is called hemiplegia, and arises from some morbid condition of the brain; when it involves both sides of the lower half of the body it is called paraplegia, and the seat of the trouble is in the spinal cord.

Hemiplegia may arise suddenly from embolus, hemorrhage, or injury causing pressure on the brain, or gradually from softening or the pressure of a tumor, or, its origin may be systemic, as from uræmia in Bright's disease. It may occur in early life from intracranial hemorrhage, pressure during birth, or the use of the forceps.

Of the sudden causes appoplexy is by far the most common, and usually occurs in advanced life, or in persons whose bloodvessels are diseased by atheroma or syphilis. The hemorrhage is most apt to occur on the cortex, and the extravasation may be small or great. If it is effused into the ventricles and is large in amount, coma is profound and hemiplegia complete.

The side of the face involved depends on the site of the lesion. It may affect the face on one side, and the arm and leg on the other, if the hemorrhage is into the pons.

While this paralysis appears to be complete, it is not always so; for the muscles of mastication and respiration often escape. Usually the muscles that escape are those which act simultaneously with corresponding muscles of the opposite side.

The reason that during recovery the leg generally improves faster than the arm, as we see in the case in this patient, is that the legs are generally used together, while the arms are not.

Appoplexy may arise either from cerebral hemorrhage, or from thrombosis caused by the washing of a clot from the heart into the left common carotid artery, which rises directly in the line of the blood current in the arch of the aorta, through the middle cerebral artery and to the left side of the brain. In most cases the vessels of the brain do not anastromose, so that when the circulation is interfered with by an embolus, softening takes place to a greater or less degree according as the circulation is cut off from more or less tissue.

In hemorrhagic appoplexy the same thing occurs from pressure; disintegration in and around the clot also attends it. In uræmia also we may have appoplexy and similar results.

Of these most common sources of sudden hemiplegia this man is a good example. At the time of the occurrence of his attack of paralysis he had been for some time at the hospital suffering from a chronic leg ulcer. He stated that he had previously enjoyed good health, and gave no family history of nervous affections. He has never had syphilis, but has always been a drinking man and an excessive smoker. On February 7 he wakened with a sense of numbness and cramp; he also had some difficulty of speech but this rapidly improved. He cannot move his left arm at all, the fingers are becoming contracted, and there is some stiffness in the shoulder and elbow; this rigidity will continue to increase.

In these cases the reflexes are at first diminished, but in a few weeks we find a condition of irritability, and you will notice that the patella reflex in this patient is much increased. Sensation he has not at any time lost, and he can readily localize a pin prick.

In using the æsthesiometer the sound side should always be first tested to ascertain the normal sensitivity of the skin, as patients differ widely in this. We find that sensation is here impaired on the paralyzed side, perhaps to an extent of one-third. Stiffness of the knee and pain in various joints, especially the shoulder, are not at all uncommon, and the affected joints may become very red and much swollen. Bed sores and other trophic changes are frequently found.

From the history and symptoms of the case at present before you, I would say that the hemorrhage had not been very extensive. There is some paresis on the left side of his face, as his smiles are one-sided and he cannot whistle.

In hemiplegia the facial paralysis usually recovers speedily, generally first of all the parts, for there are fibres of the same nerves that are distributed to both sides. After some months the muscles of the paralyzed side become contracted, and the face is drawn towards the paralyzed side; this might readily convey the idea that the case was one of crossed paralysis.

In many cases speech is affected, either from paralysis of the tongue, or from injury to the speech centres of the brain, giving the varieties of aphasia. In motor aphasia the patient cannot utter a sound; in sensory he can speak but becomes confused and utters the wrong words. The reason that aphasia is more commonly found with right hemiplegia is that the speech centre is located in Broca's convolution, the third ascending frontal on the left side.

Of this the next patient is a good example. As he enters you notice this walk. This is typical; he swings his leg with a circular motion and drags his foot. In the elbow there is some rigidity, and when the wrist is extended it is very hard to extend the fingers and thumb. He has no alcoholic or syphilitic history, but four years ago had an attack in which he became unconscious and aphasic. For twenty months he was confined to his bed, and was completely aphasic for two years. He then became able to say a few words, and continued to improve until a few days prior to his admission to the hospital on February 2, when he had a similar attack.

From this attack he has now partially recovered, the aphasia being somewhat diminished. He can now tell his name, residence, and many other things, but with great difficulty. His intelligence is not at all affected, and he has now reached the point in his recovery at which he is able to express the difficulty which he has of pronouncing, or as he calls it, "getting up" words. This improvement of speech which we observe is generally believed to be due to the education of the corresponding speech centre on the right side of the brain.

Two years after his former attack, and again just before being brought to the hospital, he had several convulsions, probably due to irritation set up around the seat of the old lesion. These are characteristic of organic change, and are similar to the convulsions seen in Jacksonian epilepsy. In this case we have no history of the nature of them, as they occurred before he was brought into the hospital, but I have no doubt that they affected the right or paralyzed side of the body.

Since our time is getting short I shall now show another case as an example of what narrow limits a paralysis may occupy. As the paralysis varies with the extent of the hemorrhage, the effusion in this case must have been very slight. The patient, as you see, is only paralyzed in the right arm below the the elbow. Sensation to touch, and the responses to electrical stimulation are, and were normal, but he could not use the fingers or wrist at all. He has to some extent recovered the power of moving the hand, but it is still very feeble; he can squeeze the dynamometer up to twenty only, with it, while with the other it registers fifty-five.

At the time he came in it was a question of diagnosis between local or central origin of the difficulty. The fact that sensation was unaffected was of itself proof of a central lesion. Then, it was very difficult to see how we could produce a local palsy of this kind, involving both flexors and extensors, by pressure on nerves supplying the part.

At the mitral valve of his heart we hear a murmur, so that there is no doubt that the cause has been a clot, washed off and carried by the blood current.

Our next patient is an Italian suffering from his third attack; muscular contraction is very great, especially at the fingers.

In a paralyzed extremity the growth of the nails is stopped, but recommences after two or three weeks, this is readily shown by staining them with nitrate of silver or nitric acid. This man's nails are ridgy at the end but smoother near the matrix, showing an improvement of their nutrition.

Electricity, as a means of diagnosis, has not in these cases proved of much account.

For Migraine.—

℞.—Quininæ sulphatis . . . . . gr. iv.
Sodii salicylatis cryst . . . . . gr. iv.
Morphinæ muriatis . . . . . gr. 1-24.—M.

Sig.—To be taken every half hour, from the beginning of the attack until four have been taken.

Immediately after the last dose, take $\frac{1}{240}$ grain of crystallized aconitine. In one-half to two hours the paroxysm will have ceased.—*Revue de Thér.*

Original Articles.

HIGHER MEDICAL EDUCATION.

By U. M. SNYDER, M.D.,
DELMONT, PA.

EASTERN Medical Journals, Societies and Academies seem, all of a sudden, to have become excited over the subject at the head of this article. They are, apparently, horrified at the deplorable intellectual status of the medical profession in this country. This is not at all astonishing. The only astonishment connected with it is, that it has not aroused attention and alarm long ago. The present state of medicines has existed in this country all through its history. It is no worse now, and no better, than it was fifty years ago. If there is a remedy for it, it will come too late for us of this generation of physicians. But for the past indifference towards an educational requirement for entrance into medical pupilage the profession would not have the illiteracy that encumbers and disgraces it, but would be resting on a higher intellectual plane. To say a higher *medical* education is a transposition of terms. Let us say a higher *intellectual culture*, by virtue of a liberal literary and classical course, and a higher professional status will of necessity follow. The former proposition would have us begin at the wrong end. It would transpose the last to the first step in a physician's career. Require of candidates for medical pupilage the same qualifications required for graduation at a respectable literary college, and they will not then want to belittle themselves professionally. Their intellectual pride would be the surest guarantee that they would not dishonor their profession. So long as medical pupilage is open to all who wish to enter so long will the profession be retarded and disgraced by ignorance and fraud. Society is more responsible and culpable for the low mental status of the medical profession than either the profession itself or the laws relating thereto. If it did not encourage quackery and unqualified practitioners by its patronage, that class of men would soon disappear. Natural capacity and broad culture are not considered essential in a country physician. If he be friendly and sociable, though he be a fool and a blackguard, a clientage will not be wanting. Has a weak but conceited young man taught a few terms in our public schools, he will have outgrown his clothes and imagine himself fitted for a profession. But, owing to the educational requirements in law and theology, he cannot gain entrance there, so he jumps into medicine. Indeed, men enter medicine from all walks of life, at all ages, without any thought as to their fitness by nature or acquirements. No matter what their occupation may be *now*, next year they may be practicing medicine. Now what conception must society have of the character and dignity of a profession that permits such easy access. Law and theology have provided their own protection against unworthy membership, but medicine stands alone and unprotected against that fatal curse. Labor, in any legitimate capacity, is not dishonorable, but I appeal to all candid persons, whether a medical student should not all his previous life have been a diligent student, so as to lay a broad and liberal culture through youth and early manhood, when the mind is most impressible and the memory most retentive. Aside from all professional considerations, for their own satisfaction they should be scholars; as through the vicissitudes of their calling, they will come in contact with scholars in all walks of life; and regret and mortification will betide them, if they be found wanting. The science of medicine is the grandest of all sciences; embracing not one only, but all the physical sciences. Particularly does it include that one fundamental, pivotal science, around which all others revolve, the sience of biology, which, if we could penetrate and comprehend, would reveal to us the mysteries of the universe.

The English language is a mongrel one, and the language of medicines still more so, yet its nomenclature is the most expressive in the world. The entire technicality has underlying it a deep primitive meaning. But what on earth would be the object of a general language or aspecial nomenclature, if an understanding thereof were not needful. How then, can one ever acquire a science whilst ignorant of the language in which it is written? Language is itself a science, and the basis of all scholarship. It touches the beginning, the middle, and the end of life. It is inseparable from the understanding and indispensable to success. The philological basis of the science of medicine is Greek, whether from the Greek directly, or indirectly, through the Latin. Yet a majority of medical students from the country think a knowledge of those languages altogether unimportant. They may learn the superficial meaning of any one word, but why it is so called is sealed to them. For aught they know, it might as well be called borioboola; it would have just the same significance to them. Take, for instance, the Greek suffix *itis*, exaltation, and we find some seventy words built upon its; the suffix denoting condition and a primitive expressive of organ or tissue, the meaning of the word is contained in its etymology, and a dictionary need not be referred to at every turn. We have in medicine nearly eleven hundred Greek and twelve hundred Latin terms, but the latter are drawn largely from the former. We have also some eighty words of French nationality, but they have come down to us, indirectly, from the Latin, as it existed in Gaul at the time of that country's invasion by the Frankish tribe of the Teutons, who overran the Roman Empire in the earlier centuries of our race. There are also a few taken from other modern languages of Europe, and nearly all with Graeco-Latin roots. Aside from the literary accomplisements that the classics give rise to in their students, they afford a most efficient mental discipline. Aside from an introduction to the languages and literature and institutions of the intellectual centers of antiquity, they develope and strengthen the reasoning faculty.

This present time is prolific in scientific word-coining, words, which as they stand compounded are not to be found in *any* dictionary. So unless we can go back to the native meaning of their component parts their interpretation must remain unknown.

Historians tell us, upon the authority of the Ayur

veda, the oldest known medical work that the laws of the ancient Hindoos exacted such acquirements in medical licentiates as few mortals ever reached. Would we had a little such exaction now.

If you would elevate the standard of *medicine, then first elevate the standard of preparatory education.*

"A little learning is a dangerous thing,
Drink deep or taste not the Pierian spring."

ELECTROLYSIS FOR THE REMOVAL OF SUPERFLUOUS HAIRS.

By H. MONTAGUE, M.D.,
DETROIT, MICH.

IN an experience extending over some ten years, I have treated upwards of fifteen hundred cases with varying success, rarely finding, though, that more than ten per cent. of the hairs return after the first series of operations.

Since the adoption of electrolysis for this purpose the operation has undergone many modifications, notably in the intensity of the current and in the fineness of the needles used.

Regarding the intensity of the current Dr. L. Brocq, of Paris, in 1886, considered as necessary a current strength of from fifteen to eighteen milliamperes; but in April, 1888, he admits that only from three to five milliamperes are necessary to obtain the best results.

In my own practice I never exceed five, and rarely employ more than three milliamperes. The outfit necessary for the removal of superfluous hairs consists of a galvanic battery, a fine needle holder and needles, epilation forceps, and above all a reliable milliamperemeter. I cannot find words strong enough in condemnation of the physician who attempts to use the galvanic current, no matter for what purpose, without having in circuit a reliable milliamperemeter. Where the Edison incandescent light wire can be made use of, the rheostat made for me by the Michigan Electrical works of this city, is far preferable to any form of battery, being cleaner, cheaper and more constant.

Almost every one practising electrolysis has his own idea of needle holder; for my purpose I prefer a long and delicate holder, resembling an artist's brush. Jeweler's brooches, Nos. 5 and 7, form the best needles for the work, and by drawing the temper they can be bent in any desired direction, thus obviating the placing of either the patient or oneself in a strained position.

I do not agree with some operators that the circuit should not be closed until the needle is inserted, as by the anodal application of a 15 per cent. solution of cocaine, I am able completety to obtund the pain resulting from the passage of the needle through the cutaneous envelope.

The length of a sitting must naturally depend upon the extent of the surface to be operated upon, the urgency of the case, and the endurance of the patient, usually in cases involving the face I limit the seance to two hours, repeated two or three times a week; in treating the arms, etc., longer, and if necessary, daily sittings can be supported. The amount of irritation created depends upon the care with which the operation is performed, and the sensitiveness of the patient's skin. I rarely find it fail to yield to hot applications of distilled extract of witch-hazel and water, one to four.

In conclusion I would say that I am convinced that in electrolysis we have not only a perfectly safe, but absolutely reliable method of permanently obliterating blemishes that have proved a source of mental anguish to many. At the same time I am not infrequently assailed with the remark, "I have tried electrolysis and it is no good." Doubtless failure is possible, but it should be attributed to the want of skill and technical knowledge on the part of the operator, and not to an operation which has been amply proved to be successful.

Regarding any scar resulting from the operation, I do not consider any such trouble possible, unless through the use of currents of too great intensity, an accident rendered impossible if a milliamperemeter is used, or through the removal of hairs in too close proximity at one sitting.

UNIQUE PRESENTATION OF A FŒTUS.

(Read April 10, 1889, at the Philadelphia County Medical Society.)

By E. P. BERNARDY, M.D.

THE patient who gave birth to this child was a primipara, aged eighteen years. I saw the case for the first time at 8 o'clock (April 8, 1889); the membranes had been ruptured four hours, the fœtus was presenting in the right oblique diameter; the presenting part seemed to be the breech, the right side deeper in the pelvic cavity than the left; the fingers could be hooked in what appeared the groin, but did not have the full feeling one would expect in breech; a sort of sulcus or fissure was in the centre of the presenting part. Passing the fingers further upward, the bone of the skull was detected. I thought that I had a double pregnancy, the breech of one presenting and the head of the other imbedded in the chest of the first. External palpation showed the uterus divided in two by a deep dent in its fundus, a large body occupying the upper left portion, and a body occupying the lower portion of the right side.

I did not introduce my hand into the vagina, for the maternal parts (vulva) were rigid, and had not undergone any softening, and such examination would have undoubtedly caused a rupture of the perineum; the os was spasmodically contracted around the presenting part. The patient not having such pain, and having to deliver a hydrocephalic case, I left her for about two hours. On my return, the entire portion, which you here see, was grasped by the vulva, and the child was delivered in this position. It will be seen that both shoulders presented fair and square, the neck, somewhat stretched, thrown forward on the chest, and the head slightly twisted sideways lying in a cavity in the chest; the arms laid on the top of the chest, right and left side, the head between. There was hardly any pain connected with the confinement.

This is a rare case; I cannot recall an instance of a similar presentation.

HUNTING THE GERM OF YELLOW FEVER.[1]

By FRANK S. BILLINGS.

(Director of the Patho-Biological Laboratory of the State University of Nebraska.)

So far as my personal experiences extend and the literature at my command will permit of my expressing an opinion, while a vast amount has been written upon this disease, still there does not seem to be one of the great human pests which has been so unsatifactorily studied from an exact and scientific point of view. While the clinical report will answer and the empirical epidemiological phenomena are passingly satisfactory, one looks in vain for an exact and detailed description of the patho-anatomical lesions. Search where we may in all the leading works, through all the leading journals upon such subjects, over-look as we may, the reports, or papers, of those so-called, and newspaper-lauded scientists, who have been especially deputed to investigate this disease, *not one single descriptive autopsy is on record.* In fact, a competent pathologist, with a knowledge of kindred diseases, and well versed in the clinical phenomena, could easily write a more accurate and detailed description of the anatomical lesions in yellow fever than any one of these observers has given us to date. It matters not what persons may think of the writer's methods or adverse opinions they may form of his character, he does not hesitate to say that any and every unbiased pathologist must agree with him that, judged by the evidence as given by themselves, and as it exists in printed works in England, Germany, France or the United States, these persons who have been engaged by government authorities to investigate the yellow fever have given the strongest testimony possible of their utter incapacity and unfitness for the responsiblities thus conferred upon them. They do not give evidence that they even know how to approach a question of this kind. They imagine themselves bacteriologists; some, because they have edited a book written by another, and found some of the fossilized editors of semi-petrified American medical journals willing to praise them, and because of this have finally been led to believe themselves authorities upon a subject their very work has demonstrated their incapacity to investigate. In this country such semi-literary pirates seem to be those particularly favored by government patronage. Such a person is Mr. George M. Sternberg, M.D., who (strange to say, like the equally notorious Hon. D. E. Salmon, Chief of the Hog-Cholera Trust of the Agricultural Department of the Government of the United States), has been employed by the Army Medical Department for about the same period, ten years, in the study of yellow fever, that that other great monopolist has been controlling the swine disease investigation market in this country. These distinguished "Dogs in the Manger," have many attributes in common. They fondly believe themselves favored among mortals as being the only persons sufficiently gifted to enter upon such investigations; hence, their great public spirit has been displayed by a secret, and some time rather public, endeavor to monopolize all the work of this kind, and to prevent the employment of any others in the same field. Again, they are alike in being equally unsuccessful in producing any creditable work, and equally successful in finding a number of worshipful organ-editors to grind out tunes to their glory.

Whoever carefully follows my endeavors to free scientific research from the Octopus-like strangulation which it is suffering under in this country on account of the untoward influence of the three great despots of American life, viz:

1. The theological devil, or what church do you go to?

2. The political fiend, or what party do you belong to?

3. The nepotistic humbug, or where were you born and in what set?

Must be aware that no matter how severe my censures may be, they are always supported not only by incontrovertible evidence, but by testimony which is well known to be reliable, by the unbiased public, and competent and observant members of the medical profession. In this case it is my purpose to pay a little polite attention to the *Octopus of the Yellow Fever Investigating Trust, Dr. George M. Sternberg*, in an address published in his special organ, *The Medical News*, Philadelphia, March 9, 1889, entitled: "*Hunting Yellow Fever Germs.*" Dr. Sternberg admits that he has been hunting for this germ for ten years, and that he has been, and still is a most unsuccessful hunter, as follows:

"You are aware that my first effort to solve the etiology of yellow fever was made ten years ago. As a member of the Havana Yellow Fever Commision of the National Board of Health, I had an opportunity to make researches which in advance of the effort I fondly hoped might lead to demonstrations alike creditable to American science, and useful as a basis for preventive and curative measures in this pestilential malady. . . . It was, therefore, with deepest interest as well as with the strongest hopes of success, that I went to an endemic focus of the disease to search for the yellow fever germ." In a previous part of the same address the speaker said: "But I must announce to you, in advance, that there is no satisfactory evidence that any one of these microorganisms is the veritable infectious agent in the disease under consideration." The reader will now please turn with me to that portion of the address where the great monopolist is speaking of what he did as a member of that Yellow Fever Commission, and I especially desire, and emphasize the fact that, the reader will notice that the language to be quoted bears direct relation to Dr. Sternberg's work as a member of that commission, and that Dr. Sternberg himself says, now in 1889, that he was fitted to engage upon the work as follows:

"I was" (then 1879) "familiar with the most approved methods of mounting and staining microörganisms, and was provided with the best high-power objectives that could be procured. . . . *Not only did I feel that I was equipped for the recognition of any*

[1]From the original MSS. of the second edition of the author's work on the "Southern Cattle Plague and Yellow Fever."

microöcganism which I might prove to be present in the blood, but I was prepared to photograph it and thus to show to others what I might see in the blood drawn from the circulation of yellow fever patients."

The above is very remindful of the remark we often hear, "that so and so has told the same story so often that he finally believes it himself." In this case it is a little different, however. It may not be that the exceedingly well advertised monopolist has been guilty of such frequent repetition of the "same story" as the "other fellow," for the above is the first time he has put himself on record as having told it, but the effects of sycophantic flattery on his egotism have been such that he undoubtedly believed all which he said of himself in his Montgomery, Ala., address, 1889, was equally a true picture of himself as he saw his own reflection when a member of the "Havana Yellow Fever Commission," in 1879; but Dr. Sternberg seems to have been so completely lost in admiring the refulgent glories of his Nihilistic course as to forget that some years previously he edited a book, entitled "Bacteria Megnin," second edition, 1884, in which is printed:[1]

"The writer's personal investigations are recorded in the 'preliminary report of the Havana Yellow Fever Commission of the National Board of Health.'"

The above is simply quoted to fix Dr. Sternberg so that it cannot be said that his remarks of 1889, above quoted, did not bear relation to that same Commission and investigation.

The reader will again bear in mind that Dr. Sternberg has told us, 1889, that "not only did I (he) feel that I was fully equipped," etc., and then be kind enough to turn to his edited publication of Megnin's work where the same author again speaks of himself and his equipment to do the work he was engaged for. Even then he does not tell us that since 1879 he thinks he has "fully equipped" himself, but he does say:

"Evidently an extended acquaintance with the bacterial organisms found during life and after death in the bodies of persons not suffering from yellow fever, *and familiarity with the most approved methods of isolating and cultivating these organisms, would have been of great advantage to the investigator. But this preliminary knowledge and special training was of the most imperfect character.*"

Certainly further comment is entirely unnecessary after such a display as that by the great monopolist of the Yellow Fever Investigation Trust, supported by the Government of the United States, an institution once fondly supposed to be "a government of the people, by the people, for the people, but in reality *a government of ignorance and indifference, by duplicity and cunning, for the benefit of trusts, monopolies, and every form of cowardly and despotic selfishness, utterly regardless and equally reckless of the interests of the people.*

The exact attitude of the governments (State and National) in the United States towards the people is most becomingly expressed in the language attributed to the late Vanderbilt: "The people be damned."

[1] Page 420.

Did the Government of the United States really represent the welfare of the people of this country; had it really the intelligence ordinarily common to men, it would never have given one single, untried, though book-reputed, individual entire monopoly over the investigation of such a terrible public curse as the yellow fever.

Persons may think I am making a personal attack upon Dr. Sternberg, and in a certain sense it does appear so, but on the contrary I am not, I am simply combatting monopoly in any field of science under government support, but especially when monopoly and incompetency have been allowed to go hand in hand for ten long years at the cost of so many thousands of human lives and so much economic disturbance. If the government desires to employ Dr. Sternberg, or any other person, on such a mission there can certainly be no objection, but if the government is in earnest let it establish a suitable laboratory in the Southern States for this kind of work, and if it is still more in earnest let it offer $50 a day and expenses to ten investigators, who must be proven men, and known to be such, to the world, and in case of death, $5,000 a year pension to their families or those directly dependent upon them, and "Hunting the Germ of Yellow Fever" will be soon a matter of the past. But to offer $100,000 for a *cure*, as was lately attempted, is but a fit example of quackery in government as well as supporting it in other things.

Let us now turn to the investigations in search of the germs of the yellow fever and begin by considering those of Freire, who read a paper giving what I suppose can be looked upon as the details of his work before the "Section of Public and International Hygiene of the Inter-National Medical Congress, Washington, 1887," and published in abstract.[1] I will not, however, use that paper but will insert a summary furnished me by Dr. John S. Billings, and published in the first edition of my report upon this disease, as it is more condensed and has the advantage of being in the exact words of the author:

Résumé de l' évolution du cryptococcus Xanthogencicus.

Millien dans leguel il vit. — "Dans le sang, dans le liquide du vomissement dans le cerveau, dans les muscles, dans les organes parenchymateux, en général en tous les tissue et humeurs de l'économie et dans les liguides de culture albumineux."

Mode de Crossnance. — Ils commencent par de petits panits noirs, qui passent à l' état cellules naulés bordés de gris ou de noir, refractants fortement la lumiére, quelque fois irisées; granulenses à l'interieur lorsgúelles sont mûrescontenants du pigment jaune et verdâtre.

Mode de Reproduction. — "Les cellules mûres se déchírent: 1° en différenté points en même temps (c'est cas le plus fréquent); 2° en un seul point less pores sortant par un seul orifice (rare); 3° par une section circulaire la cellule prenant la forme d' un pyxide" (rare).

[1] *Medical News*, Phila., Sept. 17, 1887.

Disposition des spore, des lambeaux et du pigment.

"Tantôt les spore se répandent sans ordre ; tantôt ils aherent au pigment sans disposition régulière, tantôt ils adherent in même affectant différentes figures, comme celle d'une poire, d'une pomme de pin, d'un ananas. Les lambeaux promenants de la désaggregation des cellules forment diverse amas amorphes, blancs, noirs ou vardâtres."

Résumé of the Evolution of the Cryptococcus Xanthogenicus.

Media in which it lives.

"In the blood, vomited fluids, the brain, muscles, and in the parenchymatous organs ; in general in all the tissues and humors of the economy, and in albuminous cultivating media."

Mode of growth, (appearance.)

"They commence as small black points which pass to a state of round cells, having a gray or black border which is very refracting ; they are granulated when mature in their anterior, containing a yellow or greenish pigment."

Method of reproduction.

"The mature cells divide themselves as follows :

"1. At different points at the same time—which is most frequent.

"2. Into a single point, the spores passing out by a single orifice—rare—(!!—B.)

"3. By a circular section, the cell taking the form of a 'pyxide' capsule—rare—(!!!—B.)"

Disposition of the spores ; of the segment and of the pigment.

"Sometimes the spores disperse themselves without order ; sometimes they adhere to the pigment without any regular disposition ; sometimes they adhere to each other, forming different figures resembling a pear, a pine cone, or a pine-apple. The segments proceeding from the disintegration of the cells form divers amorphous clusters of a white, black or greenish color."

So much for Freire's description. That it will not apply to any known form of bacterial life need scarcely be called attention to. That Freire, like Pasteur, is ill-fitted to enter upon such studies in the spirit of exact pathology is self-evident, but still there is an important statement in the abstract noticed above, which it will not do to overlook. Under the heading :

"Inoculability of the Amarillus Microbe" Freire says : "I have made a great number of inoculation experiments upon animals in order to prove the transmissibility of the disease." "*I have remarked that inoculations made directly both with the blood and with virulent cultures kill rabbits and guinea-pigs in from two to ten days.*"

Now this is the point ! Here is a positive statement, which in the want of positive contradictory evidence it will not do to deny, though we do not have the full particulars, that not only in the blood, but in cultures made from materials from yellow fever patients, there is a something with virulent properties, though we cannot distinguish any specific characteristics by which to recognize that object in Freire's descriptions. This does not militate against the fact which is exactly on a par with Pasteur's results and descriptions in the rouget of the hog, in which he said a coccus was the germ, but which Schûtz showed to be a bacillus, and which was also in Pasteur's virus but was overlooked by him.

I say we cannot overlook a statement like the above. Scarcely any one can doubt that yellow fever is a septicæmia, a blood-poison, and I think all competent persons will agree with me also in its being of extra-organismal origin, that is, an exogenous disease. Being thus, it is an incomprehensible phenomenon why both Sternberg[1] and Gibier[2] should be so unsuccessful in discovering any micro-organism in the blood, at least in some cases, as my own investigations have conclusively demonstrated, not only the presence of such, but of one and the same organism in the coagulated blood filling the small vessels in sections of the liver and kidneys, from several different individuals, each of whom is guaranteed as having undoubtedly died from the yellow fever, and from the liver of an eighth individual, the genuineness of the diagnosis being also unquestionable in this case as well.

Sternberg says :[3] "Ninety-eight specimens from forty-one undoubted cases of yellow fever were carefully studied, and one hundred and five photographs were made which showed satisfactorily everything demonstrable by the microscope. No micro-organism was discovered." His other and later attempts have also been "negative" as regards this tissue.

Now, these "carefully studied" cases were made when Dr. Sternberg was a member of that "Havana Yellow Fever Commission," and we have seen that when the facts as to his qualifications (1879) were still fresh in his mind, though they were completely dispelled later—1889—the necessary "preliminary knowledge and special training was of a most imperfect character,"[4] even as late as 1884, and hence may feel justified in assuming that the requisite skill to demonstrate this organism has not yet been acquired by the government monopolist. All attempts at culture from the blood have also been unsuccessful.

Exactly similar assertions have emenated from the Bi-bacterial chief of the swine-plague trust in Washington, regarding any micro-organism in the blood of cattle diseased with the Southern cattle plague, and very lately a most reliable gentleman has personally told me that they (the Swine-Plague Trust Monopolists) could not find any germ in the blood of Texas diseased cattle, but had found one like mine in the contents of the intestines. Any one who may be here can be shown the original specimens from the blood of cattle that died of this disease in several outbreaks dating back to the first investigation in 1887, and in each one of them can see absolutely pure conditions of the germ of that disease.

[To be continued.]

Hospital Notes.

MEDICO-CHIRURGICAL HOSPITAL.

ACUTE PLEURISY.

WAUGH presented a case of acute pleurisy, occurring in a man of great muscular strength, but of doubtful constitution, his mother having died of intestinal tuberculosis. He was always very thin, seeming unable to put on any fat, even when taking cod-liver oil in large doses. Under these circumstances the occurrence of pleurisy was rather disquieting in view of the well-known relationship of pleurisy and tuberculosis. Indeed, it has been held that pleurisy is *always* due to tubercle; but this exaggerated view does not harmonize with clinical observations, or else our prognostic deductions concerning tubercular affections must be radically wrong.

In the present case the patient was put to bed, kept upon a dry diet, with as little fluid as was compatible with his comfort; a small, very narrow blister was applied over the affected side, and a two-grain pill of phenacetine given every two hours. The patient made a quick recovery, and was back at his work in a week. Here was a case which might well have been tuberculous, from its antecedents, but recovered.

TÆNIA.

Waugh next showed a case of tænia. Three months previously this patient, a woman, twenty-seven years of age, was placed upon the following treatment. Just before going to bed she took one ounce of sulphate of magnesia, in water. Immediately upon rising she took one drachm of oleoresin of male fern, in capsules. This was divided into four doses, which were taken half an hour apart; and thirty minims of ether, in simple elixir, with each dose. Two hours later she was given an ounce of castor oil with thirty minims of oil of turpentine. No food was taken until after the oil had operated. The worm was voided, but the head could not be found.

Now she appears again at the clinic, telling us that the proglottides are again appearing in her stools, and she suffers the nausea, qualms, and irregular appetite which she told us of at her previous visit. The same treatment was prescribed, with one addition. On the day before she took the tænicide she was told to eat a cocoanut, which has been recently recommended for tape-worm. She did so, and this time the worm came away entire. Dr. Waugh is not inclined to attribute much virtue to the cocoanut, as none of the worm appeared until after the fern had been taken.

(Notes of Prof. Shoemaker's clinic for Skin and Venereal Diseases.)

IMPETIGO CONTAGIOSA.

The lecturer in a case of impetigo contagiosa, recommended internally milk, eggs, meat and the following:

Take of oil of gaultheria . . . . . 5 drops.
Cod-liver oil . . . . . 4 ounces.
Compound syrup of phosphates . 2 ounces.—M.
Dose: One to two teaspoonfuls three times a day.

External.
Take of distilled witch hazel . . . . . 4 ounces.
Corrosive sublimate . . . . . 4 grains.—M.

After using the lotion over the surface, the parts may be dusted with this combination:
Take of iodol . . . . . 3 drachms.
Oleate of zinc . . . . . 2 drachms.—M.

SEBORRHŒA SICCA.

In a patient suffering with dry or scaly seborrhœa of the scalp and face this prescription was ordered:
Take of sulphide of arsenic . . . . . 1 grain.
Extract of ignatia . . . . . 2 grains.
Extract of gentian . . . . . 40 grains.
Mix and divide into twenty pills.
Dose: One pill three times a day.
External.—Apply twice a week, the tincture of green soap, and at once wash off with water.
Use also, two or three times a day:
Take of fifty p. c. solution of boro glyceride 4 ounces.
Bismuth subnitrate . . . . . 1 drachm.—M.

TINEA FAVOSA.

A case of favus of the scalp received:
Take of compound tincture of cinchona . 3 ounces.
Fluid extract of malt . . . . . 3 onnces.
Tincture of ignatia . . . . . 24 drops.—M.
Dose: Two teaspoonfuls in water three times a day.
External.
Take of beta naphthol . . . . . 10 grains.
Corrosive sublimate . . . . . 5 grains.
Lard . . . . . 1 ounce.—M.

TUBERCULAR SYPHILIS.

A male patient of about forty years, with tubercular syphilis, especially of the face, neck, and shoulders, being especially anæmic and debilitated, had the following treatment:
Take of sulphate of quinine . . . . . 40 grains.
Carbonate of iron . . . . . 40 grains.
Arsenite of sodium . . . . . 1 grain.
Sulphate of strychnine . . . . . ½ grain.
Mix and divide into 40 pills.
Dose: One pill three to four times a day.
External.
Take of iodol . . . . . 1 drachm.
Beta Naphthol . . . . . 5 grains.
Ointment of nitrate of mercury . 1 ounce.—M.

SCROFULODERMA.

In the case of a little girl of five years, with enlargement of the glands around the neck, attended with several sinuses, plenty of fresh air, exercise, milk, eggs, meat, and easily digested vegetables were advised. Also prescribed:
Take of fluid extract of Hoang nan . . . 50 drops.
Glycerin . . . . . 3 ounces.—M.
Dose: One to two teaspoonfuls three times a day.
External.
Take of ointment of the oleate of mercury
(10 per cent.) . . . . . 1 ounce.
Salol . . . . . 1 scruple.—M.

HYPERIDROSIS.

The excessive perspiration, occurring in a young woman of eighteen.
Take of sulphate of atropine . . . . . 1-10 grain.
Sulphate of strychnine . . . . . ¼ grain.
Cinnamon water . . . . . 3 ounces.—M.
Dose: One teaspoonful morning and evening.
External.
Take of fluid extract of geranium maculatum . . . . . 2 ounces.
Glycerin . . . . . 2 ounces.—M.

Society Notes.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

STATED MEETING APRIL 24, 1889.

W. W. KEEN, M.D., President, in the chair.

DR. FREDERICK A. PACKARD read a Report of a Case of Spinal Hemorrhage.

Six weeks before coming to the dispensary for treatment he had fallen down a flight of fourteen steps, struck the back of his neck against the edge of the last step, and was completely paralyzed from that moment. He gradually recovered some power, and at the time of presenting himself at the dispensary his condition was as follows:

General health seems good; he eats and sleeps well; the bowels are constipated, being unmoved for a week at a time unless aided; his urinary apparatus is apparently in good working order; he has no symptoms referable to the heart; he gets short of breath easily, and, in addition to a sensation of weight upon the thorax, has a pronounced "girdle-pain;" he has not, nor has he had any vomiting or hiccough; his hearing is excellent, but his vision seems to him to be impaired; he has almost constant pain in the back of his neck, at times shooting over the occiput in straight lines on ether side; his greatest complaint is of weakness in arms and legs, most marked on left side, and of a coarse tremor occurring in all but a few positions that he assumes; he is able to walk about one block with the aid of a cane, but having accomplished that distance his right knee gets stiff and he is unable to lift the toe from the ground; he has both sexual desire and power.

Examination of the patient revealed the following conditions: Intelligent man, well nourished; speech natural; face and neck appeared entirely normal except for slight myosis. Examination of the pupils showed that they were equally contracted when shaded, but reacted feebly to light. There was no accommodative change in the size of the pupil.

Taking the history and conditions present in this case, there would seem to have been hemorrhage into and around the cord with probably also partial rupture. That the lesion was hemorrhage or in the nature of partial rupture is made certain by the sudden onset in a previously healthy man of paralysis of motion and loss of sensation. That it was high up, in the cervical segment, is shown not only by the history of complete motor and sensory paralysis below the shoulder-girdle, but also by the signs presented at the present time.

The conditions no doubt have been a hemorrhage into and around the cord at about the sixth cervical segment, with probably partial rupture of the cord on the left side of the median line. This primary effect was followed by shrinking of the clot and restoration to some extent of the abolished functions. Secondary myelitis probably then occurred with, later, the descending degeneration of the lateral columns giving the greatly increased myotatic irritability below the parts supplied by nerves from the injured area. A secondary meningitis also probably occurred about the site of the lesion giving rise to the pain in the nape, and possibly also to the "girdle-pain" of which he now complains. There are present no signs to indicate any posterior ascending degeneration, but the lesion is so high up in the cord that it would be difficult of recognition.

Concerning the reactions obtained with the galvanic current, I do not know what significance the formula 1. KClC; 2. KOC; 3. AnClC; 4. AnOC may possess. It is rather hard to see how it can indicate degeneration from polar-cell disease, since it is so widely distributed beyond the site of the lesion as to preclude the idea of direct damage to the multipolar cells in the dorsal and lumbar regions.

A CASE OF CHYLURIA.

SOLOMON SOLIS-COHEN, M.D., reported a case of chyluria evidently of a spontaneously intermitting type, for the urine cleared up under a placebo treatment consisting of gtt. iij. t.d. aq. menth. pip., thus preventing Dr. Cohen from making any extended observations. Once or twice before the patient, a negro of sixteen, had passed for some days a similar milk-colored, chyliferous urine. The urine by microscopical and chemical examinations shows a spec. gr. of 1.010, considerable albumen, fat gloludes, lymph corpuscles and bacteria.

MALIGNANT PAPILLARY CYST.

GEORGE ERETY SHOEMAKER, M.D., presented a specimen of a malignant papillary cyst of the mammary gland, of two years' growth; taken from a woman of fifty-six. During the last four months this patient had suffered much pain. The gland was heavy, tense, and stood off prominently from the chest.

On incision several ounces of thin, dark, dirty-brown fluid escaped, which probably contained much degenerated blood. There was no well-defined smooth cyst wall, but the irregular cavity was lined by prominent branching papillary growths, either projecting into the main cavity, or separated from it in groups by walls so as to form minor cysts of the size of a cherry. These brown papillomata sprang by constricted peduncles from a somewhat hardened base. This base, or what might be called the solid portion of the tumor, was found on section to be composed entirely of whitish fibrous lamellæ branching one from another, so that a piece removed for examination could not be prevented from separating into layers in handling. Virchow describes the structure of the cystic sarcoma as like that of a cabbage head, an illustration closely applicable to this tissue.

All sections examined were composed of various kinds of fibrous tissue, some quite dense, much of it embryonic. Some of this had taken on well marked hyaline degeneration, and exhibited brownish-yellow foci of decomposed blood. In other portions appeared hyaline ground substance dotted with numerous nuclei; in still others finely fibrillated quite young connective tissue, with very numerous connective tissue corpuscles. No epithelial cells were found, nor were there any nests. The bloodvessels, which were numerous, had well-developed, indeed, thickened walls; a condition not found in typical sarcoma.

Though to the naked eye, then, the growth corresponds closely with descriptions of cystic sarcoma, as given by various authors, the microscopical diagnosis has so far failed; but whatever its exact nature, its malignancy is extremely probable because of the general structure, the rather rapid growth, the presence of enlarged veins and the occurrence of severe shooting pain.

KENTUCKY STATE MEDICAL SOCIETY.

THIRTY-FOURTH ANNUAL MEETING AT RICHMOND, MAY 8, 9, 10, 1889.

DR. L. S. MCMURTRY, Danville, President; DR. STEELE BAILEY, Stanford, Secretary.

RECENT Advances in the Diagnosis and Treatment of Tuberculosis was the title of a paper by DR. F. C. WILSON, of Louisville, in which he referred to the frequency and distribution of the disease and the various methods of treating it, and showed numerous instruments and apparatus for the same. He discussed Wiegert's method of treating tuberculosis by breathing air at a temperature of 400° or 500° F. He considered the ability of the patient to do this without harm to the tissues a marvel, but it was nevertheless true. He had not yet tried it, but he meant to do so. He favored the disinfection of every particle of the sputa, and great care to avoid infection of nurse, or husband, or wife.

DR. J. N. MCCORMAC, of Bowling Green, believed in the disinfection or destruction of the sputa. For some time the Kentucky State Board of Health, of which he is secretary, has been distributing both to the laity and physicians literature to the effect that tuberculous patients should be isolated and the sputa destroyed or disinfected. It is preferable to have the patient expectorate on paper and then burn the paper.

DR. J. A. LARRABEE, of Louisville, asked if the contagion is so great as described, should we not have more cases, especially of physicians who are treating laryngeal phthisis? At Brompton Hospital there are four thousand persons treated annually, and no one of the physicians or nurses has contracted the disease. Mouth breathing he thought one of the great causes of tuberculosis, that is, the shallow breathing which follows mouth breathing.

The Transmissibility of Tuberculosis from the Lower Animals to Man was the subject discussed by DR. J. A. OUCHTERLONY, of Louisville, in a paper of considerable length and learning. This question was intimately connected with the subject of the infectiousness of the disease. The power of the bacillus to resist antiseptics is astonishing. Corrosive sublimate does not destroy the bacillus even at the strength of 1–500. The theory of inheritance has been thoroughly shaken by the discovery of the bacillus. Tuberculosis is rarely, if ever, congenital, but acquired. If the former theory was true, the prospects of the removal would be remote, indeed. If the latter is true, the prospects for the eradication of the disease are bright. We have clinical proof, also, that the disease is contagious. The object of the paper was to show that tuberculosis could be transmitted from the lower animals to man. There can be no security from tuberculosis so long as tubercular meat and milk are used. The disease is contagious, infectious, and not congenital. It is transmissible especially through alimentary canals and respiratory tract. Rabbits kept near tuberculous patients contract the disease in twenty-seven days. Rabbits suspended in cages so as to breathe the air exhaled by tuberculous cattle contract tuberculosis. The lungs are the primary seat of the infection. It may be contracted through the integument, mucous membrane, abraded epidermis, wounded and abraded surfaces. Tuberculosis in dumb animals is identical with tuberculosis in man. Transmissibility to other species is very frequent. The medical profession should inform the public of the condition of affairs and insist on the control of the meat and milk.

Speeches warmly commending the ideas presented in this paper were made by Drs. Reynolds, McCormac, and Carpenter, and on motion a committee, consisting of Drs. J. N. McCormac, Bowling Green; Dudley S. Reynolds, Louisville; John A. Ouchterlony, Louisville; and Wm. Bailey, Louisville, was appointed to bring this subject before the public.

The Importance of Rectal Examinations to Life Insurance Companies was a subject dealt with by DR. JOSEPH M. MATTHEWS, of Louisville. He considered it of great interest to life insurance companies, and to those insured in them, that the examinations be as thorough as possible. Most companies understand this, and have a long list of questions and examinations through which the applicant must go before he is admitted. No company, to his knowledge, requires a rectal examination. Many rectal diseases are incurable, and often fatal. The only thing the insurance companies do is to, in some instances, ask the question, have you had piles or fistulæ? Piles and fistulæ are generally not very serious to life as some other rectal diseases are. The doctor reported a number of cases which had come under his observation where insurance companies had lost money after a short period of insurance by neglecting the precaution of having a rectal examination made. The responsibility of the medical examiner for life insurance is a very grave one, and is too often overlooked. There are diseases affecting this portion of the body which are wholly unrecognizable save by a careful examination of the exploration of the rectum. There are diseases self limited, incurable, and always fatal. The interim between their incipiency and full development is so vaguely marked, and the insidiousness so obscure, that nothing less than a full exploration will reveal their nature. If in this interim the patient were to apply for a life insurance policy he would probably be received into the company.

DR. F. C. WILSON, of Louisville, thought it a delicate matter to ask this examination. It was with great reluctance that examination of the urine was introduced, but now no first class company fails to ask it, and it has saved them much money. He favored a middle ground. Questioning the patient, and if anything was found indicating trouble of this nature, then make the examination.

The Progress made in the Enforcement of the New

Medical Practice Act was the subject of a paper read by Dr. J. N. McCormac, Secretary of the State Board of Health. This has proven one of the most popular general laws ever passed in the State. Registration in most of the counties had been complete. Large numbers of charlatans being unable to comply with the very reasonable and conservative provisions of the statute had been compelled to leave the State, and scores of irregulars from all parts of the Union had been refused permission to practice in Kentucky. As was to be expected, the principal difficulty in its enforcement will occur in Louisville. The physicians of that city are making an organized effort to secure its strict enforcement, and there can be little doubt as to the final result. After January 1, he would publish an official medical directory of the State, giving the name, age, place of birth, address, and place and date of graduation of each physician in the State.

At the conclusion of the report the Society appropriated all the surplus in the treasury, to be used if the necessity occurs, to assist the physicians of any county where the law might be resisted in enforcing its provisions.

Syphilitic Ulceration of the Upper Air Passages was the subject handled in an excellent manner by Dr. M. F. Coomes, of Louisville.

Report on the Progress of Medicine was by Dr. J. W. Gilbert, of Lawrenceburg.

Laparotomy for Penetrating Shot Wound of the Abdomen, by Dr. David Barrow, of Lexington.

The Report on Vital Statistics was made by Dr. T. B. Greenley, of West Point.

The report of gynecology was made by Dr. W. H. Wathen, of Louisville. He confined his remarks to pelvic hæmatocele. He referred to the generally accepted definition of hematocele as blood tumor in the pelvis encapsuled within or without the peritoneal cavity. He said that all pelvic hematoceles were extra-peritoneal and thus it is not possible for hemorrhage into the peritoneal cavity to become rapidly encysted so as to form a fixed tumor in the pelvic or abdominal cavity. That the blood is mixed with lymph and coagulates so slowly that it is not confined in any one place in the cavity, but changes its position upon the movements of the body obeying the laws of gravitation. That the blood could not be confined by a layer of effused lymph immediately above it, and that, if the hemorrhage into the cavity is at all considerable, death would probably result before it could be confined by adhesions of the superimposed intestines. Intra-peritoneal hemorrhage is nearly always fatal. Mr. Tait has seen nearly one hundred cases, and they all died except two upon whom he did abdominal section. He referred to the fact that the blood never becomes encysted in intra-peritoneal hemorrhage from defective ligation in laparotomy for removal of the tubes, ovaries, etc. He gave as causes of encapsulated hæmatocele sudden metro-staxes of normal menstruation or of pseudo-menstruation following abdominal or pelvic operations and rupture of a tubal pregnancy. He said that intra-peritoneal hemorrhage really always caused by primary or secondary rupture of ectopic gestation.

He gave the symtoms and diagnosis of hæmatocele and advised against surgical interference unless the sac ruptures into the peritoneum or suppuration is imminent. If the fluctuation can be detected from below he recommended making an opening and giving free drainage in the vaginal vault, and if fluctuation is well marked above the pelvis, or ruptures occur into the peritoneum, an abdominal section should be done.

Laryngeal syphilis was the subject of a paper read by Dr. A. B. Thrasher, of Cincinnati. He said little difficulty would be experienced in the majority of cases, but occasionally the most skillful diagnosticians would be puzzled. The diseases most likely to be confounded with syphilis of the larynx are, tubercle, cancer and lupus.

In tubercle, and especially cancer, there is more pain than in syphilis. In cancer the pain is lancinating and radiates to the ear, and may be felt at any time. The voice is more changed in cancer and tuberculous disease. The classical pathognomonic syphilitic voice is usully more easy recognized when the acute observer has detected syphilis previously.

Cough is much more pronounced in phthisis than in either of the other conditions Deglutition is more impeded in tuberculous or cancerous ulceration. The syhpilitic ulcer develops rapidly in a few days; the cancerous requires weeks and the tuberculous months. Syphilis attacks preferably the upper surface of the epiglottis; tubercle the under surface; cancer the ventricular band. In syphilis there is a solitary serpiginous ulcer with sharp edges surrounded by an areola of hyperæmia; in tubercle there are numerous small shallow ulcers, or these have run together forming a large ulcer with ragged, "nibbled" edges; the cancerous ulcer appeared on the summit of an angry tumor and is surrounded by highly inflamed tissue.

In tubercle there is, as a rule, anæmia of pharyngeal and laryngeal mucosa while hyperæmia is the rule in the other affections.

Enlargement of cervical glands, anterior and posterior, is indication of syphilis and is either absent or not so marked in the other affections.

Lupus of larynx might be mistaken for syphilis, yet the disease is so rare as not to fall within the observation of most laryngologists. When the only manifestation of lupus is in the larynx the administration of anti-syphilitic remedies might be required to insure the diagnosis.

The report on surgery was made by Dr. Dr. W. L. Rodman, of Louisville. The doctor in looking over the work in this department during the past year found himself surrounded by an embarassment of riches. Senn's hydrogen gas test he considered conspicuously the most brilliant as it is perhaps the most useful. Gas finds its way out of the wound if there be perforation and burus with a blueish flame. The twelve propositions of Senn were given. Senn's discovery has greatly increased the interest in penetrating wounds in the abdomen, and in the results we find much to cheer us. Supra-public lithotomy has gained much in favor during the past year. Epicystotomy has every advantage for tumors and foreign bodies. The new cystoscope of Neitz and Leiter has rendered the diagnosis of tumors of the bladder comparatively

easy. In cystitis of the female, More-Madden of Dublin, has recommended the dilatation of the urethra, then curette the proliferating mucous membrane and apply carbolic acid over its entire surface. In iliac abscess it seems that early operation promises the most. Dermoid cyst of the neck has been recently operated upon by Keetly, of London, by cutting away a portion of the cyst wall, suturing it to the neck, and stuffing it with gauze after cleansing it thoroughly. This has resulted well in his hands and is certainly quicker and safer. Whitehead's method of operating for piles has here and there gained an earnest advocate, but will hardly supercede the ligature. Piles with prolapsus can, perhaps, be operated upon by Whitehead's method with the best advantage. Alexander's operation has fallen into disuse. It can only do good in cases of retroversion with fixation. Dr. Dudley, of New York, has recently described a new operation for rupture of the perineum. In the treatment of carbuncles, Edmund Owen, of London, uses erasion. He cuts away all slough and undermined skin, scrapes thoroughly with a Volkman's spoon and dresses it antiseptically. In this way a painful and septic mass is converted into a painless and aseptic one. Excision of carbuncles is advocated by Gesrter and others. The doctor considered it probably the best means of treating them. Colles, of Dublin, has shown that changing from the horizontal to the sitting posture in injuries to patients with fracture of the bones of the lower extremities is very injurious. A new treatment of aneurisms has been suggested by Macewen. It consists of the introduction of needles into the sac till they reach the endothelial lining of the opposite wall. The oscillation of the needles scratches the endothelium and causes proliferation of the leucocytes which are said to form a firm fibrous mass. Pneumonotomy is gaining laurels for pulmonary abscess, 50 per cent. of the cases being successful. Pneumonectomy has met with such success in the lower animals that it is recommended in man. One lobe or a lung may be excised. It is thought that the minimal respiratory area compatible with life and health amounts to two pulmonary lobes. The past year has witnessed many sharp discussions as to the comparative merits of ether and chloroform. The latter has not suffered by the comparison. It is not desirable that one should supplant the other as we need them both. One is good in some cases and inferior in others.

Acute Traumatic Tetanus, was the subject of a paper by Dr. R. C. McCord, of Lebanon. He related some cases and gave the results of treatment. He considered the bromide of potash the best of all known remedies.

Dr. L. H. Clarke, of Lexington, had had half a dozen cases in his practice and all proved fatal. He believed all cases traumatic.

Dr. Ap. Morgan Vance, of Louisville, had seen a good many cases of traumatic tetanus but had seen but one get well, which case he reported.

Dr. J. C. Carpenter, of Stanford, favored nourishing his patients. He kept them drunk on whisky so as to relax the spasms. One ounce of bromide of potassium in twenty-four hours had cured many cases.

Dr. J. G. Brooks, of Paducah, reported a case of traumatic tetanus which occurred in his practice while in the Hawaiian Islands. It was a Chinaman who was about to die, and was a case demanding kill or cure treatment, as the man was suffering terribly and begging to be killed. He gave him five grains of morphine hypodermically. The next morning he was awakened by a crowd of Chinamen who announced to him that the man was much improved. Two years later he was still all right.

Dr. J. A. Larrabee, of Louisville, said he had nine cases, four successful, and all children. He thoroughly believed that any case would yield to bromide of potassium provided the remedy was given in sufficient dose. To the educated physician dosage is simply a botheration. He knows the physiological action and gives for results. The pathology of the disease is unknown.

Dr Dudley S. Reynolds, of Louisville, was surprised to hear that any one thought the pathology of traumatic tetanus unknown. It was settled at the Second French Congress of Surgery which met in Paris, in 1886, by Prof. Cornil, who presented the streptococcus as the cause, and his demonstration was so perfect that the Congress coincided totally with his belief. This great discovery should not be passed over lightly.

Dr. J. M. Mathews, of Louisville, thought the pathology of traumatic tetanus still very unsettled. He believed there was more to be learned by the report of cases. In one case he had given bromide of potassium in sixty-grain doses every second hour for seven days, and continued the dose at greater intervals. At the end of three weeks he was able to go home.

The Management of Wounds was the subject of a paper by Dr. C. C. Skinner, of Louisville. He favors irrigation.

Dr. T. Hunt Stuckey, of Louisville, thought that in some cases, circumcision, for instance, irrigation favored œdema. He thought the dry dressing better in this case.

The Report on Otology was made by Dr. J. M. Ray, of Louisville. He thought that medical men were now giving more time and attention to ear diseases. Many still treat the ear without giving the nose and throat especial study. The deaths of prominent men of disease of these parts has called attention to these troubles.

Dr. J. G. Carpenter, of Stanford, thought the more aseptic and antiseptic we were, the sooner will these troubles heal.

Dr. John Young Brown, of Henderson, reported a case of operation for impermeable stricture.

Dr. J. M. Foster, of Richmond, thought that the time was near when external urethrotomy would be a more common operation.

Dr. A. W. Johnstone said Coxe's operation, though difficult, was not so much so as most men thought. He had made it three times and all patients were living. A little courage was necessary. He was in favor of the use of the aspirator and trocar in some cases.

Dr. W. L. Rodman, of Louisville, favored the use of the aspirator.

Dr. E. S. McKee, of Cincinnati, read a paper on Prolapse of the Ovaries. This disease he thought much more frequent than is generally considered. He said it was a symptom often rather than a separate disease, yet it had many peculiar characteristics which entitled it to distinct consideration. The dislocation may occur into the lateral pouch of Douglas, the true pouch of Douglas, and the anterior or vesico-uterine pouch, or the infundibulum of the inverted uterus. The last position is seldom found, and the next to the last is one of rarity.

Causes which lead to this trouble may be increase of weight which induces traction from below or pressure from above; causes which produce feebleness or lengthening of supports, as the conditions present during the puerperium, congestions, displacements, particularly the posterior ones, or violent straining at stool. The left ovary is more often prolapsed, because of its greater enlargement during pregnancy, and because it is more subject to disease. There are several reasons for this fact in connection with this ovary, the principal one being the valveless state of the left spermatic vein which renders the vessel easily affected by an obstruction in the circulation.

Marked pain on walking, on coition, with torturing pain on defecation are experienced by the patient, and occasionally hysteria and melancholia. Spasms of sickening neuralgic pain are felt in the pelvis and surrounding parts.

The displacement of the ovary usually occurs in this manner: It sinks downward and backward and describes an arc toward the median line. The fallopian tube and ovarian ligaments form cords. The descent of the ovary brings it to that part of the pelvic fossa known as the retro-ovarian shelf, where it may remain.

Usually diagnosis is not difficult. If found easy the patient should be examined on the left side, as the finger reaches at least an half inch farther up the posterior vaginal wall in that position. An anæsthetic may sometimes be of service. Rectal examination will allow the finger to reach an inch higher up into the pelvis than per vaginam. The elevation of the pelvic contents, en masse, must not be mistaken for mobility of the ovary.

The prognosis will depend on the condition of the ovaries, the presence or absence of complications and the duration of the disease.

The author considered Campbell's position on the knees and chest of much benefit as one of the means of treatment. He thought pessaries do more harm than good. The intestines should be kept empty with some preparation of mercury. If sexual intercourse be permitted at all it should be carefully regulated. Superior advantages result from Bozeman's method of columning the vagina with the patient in the knee chest position. He discussed Schultze's method, but considered it still under inspection. Oöphoraphy was an operation of much merit in the judgment of Imlach, of Liverpool, but other writers do not accord with him. Tait's operation had not been followed by the permanent good results expected. The essayist had seen prolapsed ovaries follow the ascending uterus as it escaped from the pelvis at the fourth month of pregnancy, and after delivery they remained in the proper places. Hysteroraphy affords relief to some cases, and sometimes as a *dernier resort*, extirpation becomes a necessity.

The attendance was good, and the meeting from the first promised to be an unusually good one. Reports of the Secretary, Treasurer, Committee on Arrangements and other committees were briefly made. Ex-Governor James B. McCreary was present and made a speech in which he extolled the medical profession very highly. He had served with them in the pursuits of peace and of war, in the legislative halls of the State and nation, had yielded his place in the gubernational chair to a doctor, and one of this profession from his own city of Richmond, now occupied the office of Chief Justice of the United States.

On motion it was voted to appoint a committee of reference in each County of the State to see to the enforcement of the new medical law by proceeding against all violators, and to use the money in the treasury of the Society for the prosecution of these offenders.

On motion the national formulary was endorsed. A committee consisting of Drs. J. G. Carpenter, of Stanford, Steele Bailey, of Stanford, and H. Hunt, of Lexington, was appointed to attend the meeting of the Pharmaceutical Association at Crab Orchard, May 15.

A motion to hold the vote for officers with closed doors, and by ballot, instead of committee, was voted down.

Officers elected were as follows: President, John A. Ouchterlony, Louisville; First Vice-President, Wm. Jennings, Richmond; Second Vice-President, R. L. Wilis, Lexington; Permanent Secretary, Steele Bailey, Stanford; Assistant Secretary, John Young Brown, Lexington; Treasurer, J. B. Kinnard, M.D., Lancaster. Henderson was chosen as the next place of meeting, and J. S. Letcher as chairman of the committee of arrangements.

On the first evening of the session an elegant hop was given at the rooms of the Madison Club, and a banquet was served at the Garnett House, on the evening of the second day. The master of ceremonies was, Dr. Jennings, of Richmond. Toasts were responded to as follows: Our Guests, Ex-Governor McCreary, of Richmond; Medical Education, Dr. Dudley S. Reynolds, of Louisville; The Young Doctor, Dr. J. M. Mathews, Louisville; The American Doctor, Dr. W. H. Wathen, Louisville; The Kentucky Doctor, Dr. L. S. McMurtry, Danville; The Absent Ladies, Dr. O. D. Todd, of Eminence. The banquet was a success.

Dr. Ap. Morgan Vance, made an interesting discourse on the subject of, The Art of Asepsis. He showed the paraphernalia of the art and a very convenient case to carry with you when making calls or going into the country.

The report on Medical Ethics was made by Dr. Dudley S. Reynolds, of Louisville. He had looked into the requirements of this and other medical societies and found them quite exacting. Ethics are not law. The ethical penalty is, censure, expulsion, ostracism. Ethics have no control over a man's prop-

erty or personal rights. He thought the Code of Ethics excellent and that the secretary should place in the hands of every member of the Society a copy, and send it into the counties where there was no society.

Dr. Larrabee, of Louisville, had never heard that hydra-headed monster, medical ethics, made so pleasant as by Dr. Reynolds. He considered ethics, the conduct of gentlemen. If a man is a gentleman, he will need no ethics. If not a gentleman, ethics will not make him one.

The report on Ophthalmology was made by Dr. S. G. Dabney, of Louisville. The advance during the past year, though not brilliant, had been steady. Cocaine has fairly held its own. The cataract operation with iridectomy was carefully discussed, and antiseptics in eye practice.

Greetings were sent to the Michigan and Kansas State Medical Societies then in session.

A Case of Tubal Pregnancy which Advanced to Term without Rupture, was the subject of a report by Dr. Arch Dixon, of Henderson. The case was one of exceptional difficulties of diagnosis. There was an enlargement which he thought an ovarian cystoma. He determined to make an exploratory laparotomy, and to his surprise opened up a sac which contained a macerated fetus at full term. The postmortem showed a case of tubal pregnancy with no trace of any rupture. The case was a very rare one, and some deny the possibility of such occurring.

A Case of Tubal Pregnancy was also reported by Dr. Charles M. Mann, of Nicholasville. His case resulted fatally and a postmortem was held.

A Case of Extra-uterine Pregnancy, was reported by Dr. J. B. Evans, of Rileys Station. He was of the opinion that the ovule can become impregnated before it reaches the Fallopian tube, and then get into the abdomen. He believes the Fallopian tube can be contracted till it will admit of the passage of the spermatozoids, but not of the ovule. He reported a case of extra-uterine pregnancy in which a patient suffered long with peritonitis and passed fetal bones and other structure per rectum.

Dr. W. H. Wathen thought the case of Dr. Dixon unique, and could not see how it could possibly occur that an extra-uterine pregnancy could be carried in the tube for this length of time. The tube walls are so thin and weak that by the twelfth week the tube ruptures and the fetus escapes into the abdominal cavity. He was sorry that Dr. Dixon did not make a thorough examination of the lining of the sac. He agreed with Tait that there was no possibility of an extra-uterine pregnancy unless it occurred in the tube with possibly a chance for an ovarian pregnancy. It is utterly ridiculous to talk of an abdominal pregnancy occurring primarily. It has never occurred and it never will occur. Extra-uterine pregnancy as is tubal primarily. We have the electrical treatment and the operative treatment. He does not believe it possible to absolutely diagnose extra-uterine pregnancy before the twelfth week. It is mere guess work before this time. He reported cases where physicians had fallen into error in diagnosing extra-uterine pregnancy when it was intra-uterine. He argued against the treatment by electricity and said the only treatment was, where rupture occurs, operate at once and treat the case antiseptically. If it does not rupture, then laparotomy is the treatment.

Dr. J. G. Cecil, could not understand how it was possible for Dr. Dixon's case to go on as he thinks it did. He thought a very fine dissection and microscopical examination would be necessary to substantiate the diagnosis. He could not agree with Dr. Wathen and Tait, that there can be no primary cases of abdominal pregnancy. Undoubted cases are on record, and Tait is aware of them but fails to refer to them in his book. He thought the only thing which could be done was to perform abdominal section. The subject was further discussed by Drs. J. M. Foster, of Richmond, and E. S. McKee, of Cincinnati.

The report on the Progress in Obstetrics, was made by Dr. J. C. Cecil, of Louisville. He discussed in an able manner, antiseptics in obstetrics, the delivery of the aftercoming head in which he would hasten the delivery of the head with the forceps, even at the expense of the perineum and cervix. He discussed the third stage of labor, and the methods of Credé and Ahlfield. He mentioned Berry Hart's theory and recommended a compromise between Credé and Ahlfield. He waits till the placenta separates, then if there is any delay uses Credés method. He discussed Cæsarean section *vs.* ovariotomy, and quoted from Busey's paper that the former was proper in all cases where child was living. Favored abdominal section over electricity in extra-uterine pregnancy.

TENNESSEE STATE MEDICAL SOCIETY.

Dr. T. J. Hupple, of Trenton, in the chair.

The Tennessee State Medical Society met in its regular annual session at Nashville, April 30 May 1 and 2. The Secretary, Dr. D. E. Nelson, of Chattanooga, at his desk.

The treasurer reported $160.68 in the treasury. Much attention was paid to legislation, and it was reported to the Society that as the results of forty years' labor the Legislature had at last been persuaded to pass a law regulating the practice of medicine. Though this was far from perfect, yet it was a great gain, and all should give it their hearty support. The following gentlemen were recommended to the Governor for appointment as a Board of Examiners: Dr. S. C. Deadrick, Knoxville; J. S. Murfree, Murfreesboro; D. D. Saunders, Memphis. A resolution requesting the Legislature to pass the bill now pending requiring the registration of births and marriages was passed.

Election of officers resulted as follows: Dr. Duncan Eve, Nashville, President; Drs. Henry Berlin, Chattanooga, James S. Neil, Marshall, and J. P. S. Walker, of Dyersburg, Vice-Presidents; Dr. E. D. Nelson, of Chattanooga, Secretary, and Richard Cheatham, of Nashville, Treasurer. The next meeting will be held at Memphis, the second Tuesday in April, 1890.

JABORANDI IN ERYSIPELAS.

THIS drug was recommended some years since, as a specific for erysipelas. It has been used extensively, and the reports, obtained from a number of physicians in all parts of the country were almost uniformly favorable. Occasionally a failure occurred, but this was attributed to the inferior quality of the drug employed. For over two years it was given for every case of erysipelas which occurred in the writer's practice, without a failure or, indeed, any unfavorable action.

During the past winter, however, a failure occurred, under circumstances which render it desirable that a record should be made of the case. The patient was a lady, aged sixty years, of good constitution, but broken in health, as a result of long-continued malarial toxæmia, and with a very feeble heart. She had had some œdema of the lower extremities for some months. An attack of erysipelas occurred, beginning on the neck and spreading over the face and to the scalp. Several bullæ formed on the cheek, and the eyes were closed for several days. Withal, there was but little fever, the eruption was not vivid, nor was it painful. The condition was one of great depression, mental and physical. From the outset, she was given the fluid extract of jaborandi, in doses ranging from twenty drops to one fluidrachm. Digitalis was also given in such doses as the condition of the heart required. The effect of the jaborandi upon the erysipelas was almost nothing. In spite of as large doses as the patient's condition warranted, the disease spread continuously. Nor was the ordinary action of the drug upon the perspiration and the saliva manifested in the usual manner. Even doses of a drachm produced but slight increase of these secretions. The patient recovered rapidly when iron was given in full doses, and also applied locally.

In a subsequent case, occurring in a woman, thirty-five years old, of robust frame, the erysipelas presented the same characteristics, but was somewhat more acute in its development. It was not until doses of two fluidrachms of the jaborandi were administered that free diaphoresis and salivation were induced; but that proved the death-blow of the erysipelas. The woman recovered in a week.

In regard to the first case, it is uncertain whether the failure was due to the poor quality of the drug, or to the condition of the patient. The latter appears to be the most probable supposition; and this is strengthened by a report received from a California physician, who had several failures with jaborandi in cases whose description coincides with that given above. If this be verified by more extended experience, the observation will prove almost as valuable as the original discovery of the virtues of jaborandi in erysipelas; as an important contra-indication will be thereby established. It is much to be regretted that the continuous introduction of new remedies leaves the profession little opportunity to thoroughly investigate the properties of one, before it is thrust aside and forgotten.

MODERN MATERIALISM.

A CHARACTER in "Robert Elsmere" says: "In my youth men talked of Ruskin; now they speak of drains." The Baconian philosophy embodies the spirit of the present age. Utility is the cry; speculative philosophy is at a discount. Fine-spun theories concerning the nature of disease, and those high-sounding terms with which we once cloaked our ignorance, have given place to the practical employment of the senses, and rational deductions therefrom. "Epidemic influences," "visitations," "atmospheric constitutions," etc., are fast following demoniac possession and witchcraft down the road that leads to oblivion. It really seems at last that man has concluded to open his eyes and look about. Plumbers tell us that what we call sewer gas, and blame on the lack of ventilation of sewers, is often derived from deposits of filth situated in the bend of the pipe just under the water-closet seat; deposits which can be easily removed. "The waters of affliction come from the family well." Malaria is a myth; a name given to the results of bad ventilation, bad housekeeping, or bad plumbing. Typhoid fever and diphtheria are not visitations of Providence; they are indications of the neglect of home hygiene, and indicate not so much the exhibition of drugs as an investigation of the water supply. Epidemics of cholera and yellow fever are not evidences of God's wrath on account of national wickedness (natural as that deduction appears), but the inevitable result of neglect of public hygiene; a result which can be foreseen and prevented whenever a community shall have advanced sufficiently in the scale of civilization to appreciate and take home to their daily lives the truths of sanitary science.

In this development no single element has contributed so greatly as the general acceptance of the germ theory. The ready explanation which it gave

of many hitherto mistily comprehended phenomena not only brought scientific minds down from the cloud-lands of speculation to a solid bed rock, but it harmonized so aptly with the little sum of true knowledge possessed by the uneducated masses that its general acceptance was instantaneous.

Like the Darwinian theories, it furnishes an illustration of that wonderful allegory in "Wilhelm Meister," where the child who had no skill in laying stones to form pictures, finally brought one which, placed at the intersection of many converging lines, suddenly unified the whole system and developed the design.

Dr. William W. Keen has been elected to succeed the late Dr. S. W. Gross as Professor of Surgery in Jefferson Medical College. This will be received with pleasure by the many friends of Jefferson and of her new Professor. Eighteen years ago Dr. Keen's brilliant lectures filled the old Chant Street School of Anatomy to overflowing; and many, like the writer, acknowledge the debt they owe to Dr. Keen for his thorough teaching of anatomy. To those who have not had the pleasure of hearing him recently, we can say that the lapse of years has only matured his ability as a teacher. He comes to this high position in full vigor, and at a specially advantageous time, when the advance in her medical course marks a new era in Jefferson Medical College. No fitter selection could have been made.

Annotations.

AT THE FOOT.

We remember once to have had a schoolmate who managed without much difficulty to keep his place at the foot of the class; and he was rather proud of it too, since it was the most conspicuous position next to that of the head.

Spain easily maintains her position at the foot in nearly every branch of progress pursued by the great class of civilized nations, so we are not much surprised to read the letter in the *British Medical Journal*, written by an English medical superintendent, recounting a visit to a Spanish insane asylum. "The first thing that greeted me," he says, "upon entering was a decidedly suspicious whip, to which were attached five or six lashes; this lay in a very conspicuous position in the attendant's room at the entrance."

He further states that the building was of the crudest description, with no furniture except benches around the walls. In that portion of the building devoted to dangerous patients he found only one occupant. "The ponderous bolts having been withdrawn, the door of his cell was opened and revealed him in an absolutely nude condition; his sole bedding consisting of a loose litter of straw, from which he arose at our appearance, and came forth with an inane smile to shake hands. On his emerging from the straw, I noticed that he had a pair of iron anklets securely riveted on his ankles behind, and attached to each anklet was an iron ring, through which a heavy bar of iron passed; so that in endeavoring to walk, he could not move one foot more than six inches before the other, and that with difficulty. I have no doubt the man may have had occasional periods of excitement, but as far as I could see, he appeared to be a very harmless dement."

ARE THERE ANY "ALLOPATHS"?

Nearly every medical journal has printed the important opinion given by Judge Barrett, to the effect that a homœopathic physician has no legal right to make use of other than homœopathic remedies without full agreement with his patient. The learned judge makes use several times in the course of his letter of the terms "allopathist," "allopathy" and "allopathic," being doubtless much better versed in the history of law than in the history of medicine, else he would know that the "allopathists" were a small class of presumed physicians who died out some hundreds of years since, and that the title of those whom he designates as "allopathists" is properly "regular physicians," men who are graduates of a regular medical college, and who are not supposed to practise according to any "pathy," school or dogma, but who, for the relief of disease, make use of any of or all the abundant stores of knowledge and remedies gained through the ages, whether by accident, by empiricism, by theory, or by scientific investigation.

THE DENTURE OF THE FUTURE.

In the course of an article in *Items of Interest* on Teeth from a Zoölogical Standpoint, we notice this sentence: "Civilized man with his cooked food and knives and forks, has little or no use for projecting cuspids or cutting teeth, and the man of the future will doubtless have less teeth than we have." This is, of course, the scientific way of looking at the matter. It is in accordance with one of the great principles of evolution—if an organism has no further use for a certain part, that part atrophies, and in time is wanting. If posterity will not use their incisor teeth in taking bites, these teeth will disappear; just as the canines are now waxing less, from the fact that we do not have to make a meal off our neighbor's cat, tearing it loose from limb after the manner of our blue-blooded prehistoric ancestors. If these teeth, however, shall in the future be counted among the missing, our descendants will hardly be winsome looking to our spiritual eyes, especially when they smile, and the small boy will not be able to whistle through his teeth.

But we do not take this gloomy view of futurity with its apprehended dental gap; and although it would doubtless please the heart of many a young mother to hear that the "coming man" will not have to go through the trying process of cutting his eye teeth, mature deliberation has convinced us that this famous man will not present anteriorly two smooth Venetian-red gums, but that these gums will be armed with teeth, big molar teeth, each with four roots and five cusps.

This prophecy is based upon another great modern biological principle—the survival of the fittest. Man kind is naturally gregarious; and as the years go by the tendency is noticed to become more and more strong for them to congregate in the large towns and the great cities. Many in these large places eat at restaurants.

Those who dine at home, who fare sumptuously every day on liquid soups, soft entrees, tender meats, succulent vegetables, and the like, must, in the course of time, under our first great principle, degenerate into a class of beings having few or no teeth, because there is no use for such organs.

These foods being easy to digest will give the stomach an easy time of it, so that this valuable organ is likely to grow lazy and worthless, and in the end our sumptuously fed people will be served with foods, each dressed with its appropriate digestant; pepsin, pancreatin, ingluvin, oxgall, or what not, and they will be a weak and puny set.

Not so with the restaurant-fed man; he toils while earning his quarter, and he sweats while eating it up. His masseters stand out like columns on his face, and his temporals are as the wings of a dragon. His molars must come together with the resistless power of a hydraulic jack, ere his beefsteak is impressed. Even after the expenditure of enormous muscular effort that bite is only imperfectly masticated, and his gastric juice and his pancreatic juice and his bile must be of well-nigh poisonous strength before they are able to separate the coherent molecules of that leathery mass. There will be grants in those days. Evolution is a slow process, but the restaurant feeders will, in the course of ages, develop into a race that will have nothing but molars all the way around, as many sets as the individual may require, and each separate tooth formed of irresistible adamant.

THE OLDEST BOOK IN THE WORLD.

PROBABLY the perusal of no other book of its length would give one so just a conception of the mutations of ages, as that of the little book with the title given above, (*Bibliotheca Sacra*). Without entering into arguments in proof, it seems shown that this work was written fully two thousand years before the Christian era, and is the oldest production in the form of a book extant. It is by the hand of one Ptah-hotep, a high dignitary at the king's court, a man who had reached the great age of one hundred and ten; and while passing his latter days in private life, he wrote these valuable precepts, addressed principally to his son. By these writings we find that the Egyptians must at that time have attained to an astonishingly high degree of culture both in society, ethics, and religion.

The machinery of government was seemingly as complete as it is at present in any country; departments of various kinds existed with their chiefs and subordinates; and the extent to which literature was cultivated may be conjectured by the fact that there was an official with the title of "Governor of the House of Books."

Several of Ptah-hotep's precepts are startlingly like those we are familiar with, from Solomon, of much later date. For instance,

> If thou are among persons who are sitting down to eat at the house of one greater than thyself, take what he gives thee, bowing low. Look at what is before thee, bowing profoundly. Look at what is before thee; do not look at it frequently; he is blameworthy who breaks this rule.

Compare Proverbs, Chap. XXIII, I.

> When thou sittest to eat with a ruler, consider diligently what is before thee.

We are also surprised to find the venerable author referring to the deity almoust without exception in the singular number.

> If thou humble thyself in obeying a superior, thy conduct is wholly good before God.

And,

> If thou art a wise man, train a son who will be well pleasing to God.

His conception and the conception of his contemporaries of an overruling power, at that far distant time, long before even Abraham lived, must have been much higher than we had imagined.

Is it not singular that these laws, customs, culture and refinements should have disappeared so utterly from the country that gave them birth; to be followed long after by the brilliant civilization of the Greeks, and then its collapse; afterwards the Roman civilization, of hardly less lustre; and it in time passing out of existence. Can it be that history will still repeat itself, and that at some future time the world will again be inhabited by hordes of barbarians?

TASTELESS QUININE.

THERE is a firm now manufacturing and widely advertising in this country a "tasteless quinine," which tasteless quinine, says the *Druggists' Circular*, is tasteless simply because there is no quinine in it. Careful analysis has shown this, and yet at least one medical man has not hesitated to commend this preparation. Physicians should be very guarded about attesting the virtues of a composition, the real constitution of which they are ignorant.

"DR." OR NOT.

THE *British Medical Journal* contains several letters each week on this well-worn subject: who shall or who shall not be allowed to add the title "Dr." to their name? Some think that these should have it, and others are quite sure that those should not. In fact, so many suggestions have been offered that we have gotten lost, and in despair offer one ourselves—namely, that they imitate our example, and grant the title to each one who is licensed to practise medicine.

AT a meeting of the Anatomical Society of Nantes, Prof. Laennec exhibited specimens of a case of cerebral syphilis, which had developed sixty years after the appearance of the chancre.—*Gazette Medicale de Nantes.*

Letters to the Editor.

DROPSY.

A BROTHER practitioner in an essay on dropsy remarks: "This disease as the readers of the ——well know, arises from different causes, therefore we should meet the indications of this disease as in other diseases." In contra-distruction to the theory of the doctor we were instructed that dropsy, a watery infiltration of a part, is merely a symptom of a disease and not a disease within itself. It is the result of a valvular lesion of the heart, disease of the kidneys or any other disease wherein the pathological changes occuring produce osmosis of the serous portion of the blood into the subjacent cellular tissues of the body or into the cavities. As he affirms, "we should meet the indications;" and peradventure it be skilfully done, we do not expect that there would arise any occasion to treat the condition known as dropsical. A. L. SAYLOR, M.D.

NORTH POWDER, Ore.

WE have received a copy of a letter from Dr. Jacob R. Ludlow, of Easton, Pa., to Dr. George W. Neff, on the oleomargarine bill. Dr. Ludlow does not approve of the inspection or taxing of oleo factories, or of any legislation on the subject; looking upon oleomargarine as "one of the most valuable forms of food that modern skill and science has been able to produce."

The Inquirer.

MEASLES COMPLICATED WITH CHIDBIRTH.

MRS. M., whilst in her ninth month of pregnancy was attacked by a severe form of rubeola accompanied with great dysponœa. Sordes collected on her teeth from the first; tongue dry; great thirst.

When the eruption was well out labor pains began, and in six hours a dead child was born, having on its body an eruption as severe as that on the mother. In a few hours after the birth, the mother's eruption suddenly disappeared, resulting in dangerous dysponœa and apparent collapse, with wandering delirium. A diaphoretic brought the eruption out again, when suddenly the lochia stopped, delirium continued, and in thirty-six hours she succumbed in spite of my efforts.

I should like to know if any of my professional brethren have treated such a case successfully, as this is for me the first of its kind in a practice of over eighteen years. WM. HENRY, M.D.

HARMON, ILL.

SUGGESTIONS WANTED.

MRS. H., aged twenty-four; weighs 194 lbs.; plethoric habit; irritable and impatient; never had any children; has been married nineteen months. Five months after marriage she was standing on a chair arranging a Christmas tree when she slipped and fell to the floor. Upon arising she complained of pain in her back. Menstruation ceased for four months, and she supposed herself pregnant. During this time she had a constant, dull headache, and at the expiration of four months her menses returned irregularly up to two months ago, when they appeared regularly.

About the time of the fall she noticed that she required large draughts of water to quench her unusual thirst, and also that a large amount was voided during the night. This state of affairs has been going on continually ever since; and at the time I first saw her, about one month since, she was taking one gallon every night and voiding two gallons before morning. No account has ever been taken of the water drank during the day. Since she has been drinking so much she has improved in weight; health and appetite are good.

Such was her condition when I first saw her. I gave her ergot fluid extract, ʒi, t. d., with no apparent result; I then put her on ergotine and zinci valerianas in capsules. This she has been taking for three weeks with the report that she feels better now in every way, not so irritable, etc.; but there is no diminution of the thirst. She takes medicine with many protests, and I am at my wit's end now what further to do. GEO. W. C.

A THORACIC ABSCESS.

MR. S. P., aged fifty-four years, of good stamina, a farmer. Was taken sick last November with what the doctor called a fever. Then a few days afterwards in the left axillary space a swelling appeared like that of an ordinary boil. His treatment was calomel, lactopeptin, whisky, diluted phosphoric acid and wine, with a small opening made through the cuticle over what was considered a boil.

This line of treatment, though there occurred one or two hemorrhages from the bowels, was continued until January 11, when I, with my father, were called in consultation to see the case. We found the man greatly emaciated, prostrated upon bed, pulse 120°; range of temperature from 2½ to 3½ degrees above normal; tongue dry, fissured and exceedingly red. A pus cavity extended from left axilla obliquely downward to the seventh intercostal space. For thirty days had this abscess been forming until now the pyogenic membrane was entirely upon the pleura. The drainage was a small pin-hole outlet in the axilla. The pus had not found its way into the pleural cavity, probably because it was corralled by a pyogenic membrane. We made free incisions into the third, fifth and seventh intercostal spaces, then with a fountain syringe, thoroughly washed out the cavity with warm carbolized water, as well as possible, and with a 1–1000 bichloride mercury solution, dressed with iodoform and absorbent cotton, and gave internally syr. iodide of iron.

Two days afterwards I found large quantities of pus were continually discharging, and that he did not tolerate well the syrup iodide of iron. Put him upon Goodell's four chlorides; continued the washing with the carbolized water. Instead of the mercuric solution gave:

℞.—Balsam Peru . . . . . ℥ij.
Olive oil . . . . . ℥ij.
Iodoform . . . . . ℥j.—M.
Sig.—With a small ear syringe fill the cavity, and wait for its own drainage; continue the iodoform dressing.

Left the patient now in the hands of his former physician.

On the 27 of January was requested to take charge of the case. Found the patient had improved for a few days since my last visit. Now has increased pulse rate, a higher temperature, no diminution in quantity of pus discharged, more emaciated, with gloomy forebodings. I continued the carbolized water, substituted listerine for the balsam Peru, and resumed for a few times the mercuric solution. Put him now upon the vegetable alteratives, adding iodide potassium x. gr. every four hours. I should have said that he was fed with nourishing food to the full capacity of the digestive organs, and yet we could not lessen the discharge, nor build up muscular strength. We continued the carbolized washings, kept all openings free, and stopped the listerine, prescribing instead tincture iodine, but with no better results.

By this time, February 17, we had gained nothing. The nervous centres flag, the mind succumbs, and dementia follows; the kidneys respond slowly, a large quantity of muco-purulent matter deposits in the urine. In a word, the patient is given up by anxious friends.

A fearful cough supervenes, large quantities of pus are expectorated. The pyogenic has given away, and we have the chest wall filling up with pus.

We now tried this plan of treatment:

℞.—Sulphite calcium . . . . . gr. ¼.
Sig.—Every four hours.
℞.—Iodide of potassium . . . . . gr. xx.
F. E. sarsaparilla . . . . . ℥j.
F. E. snake root . . . . . gtt. iij.
F. E. stillingia . . . . . ℥j.—M.
Sig.—One dose every two hours.

℞.—Lithiated hydrangea . . . . . ℥j.
Benzoata of soda . . . . . ℥ij.
Acetate of potash . . . . . ℥j.
F. E. pareira brava . . . . . ℥j.—M.
Sig.—Teaspoonful, repeated every two, four, or six hours, as required to stinulate kidneys.

℞.—Syr. sarsap . . . . . ℥ij.
F. E. wild cherry . . . . . ℥iv.
F. E. serpentaria . . . . . ℥j.
Sulp. morphia . . . . . ♏ij.
Simple elixir . . . . . ℥iv.—M.
Sig.—Teaspoonful as required to check cough.

The washing out of the cavity was kept up at regular intervals followed with a strong solution of Labarraque's solution of chlorinated soda, which acted like magic in destroying the pyogenic microbe. The other remedies responded to their utmost. The system reacted, the man was saved; to-day, April 8, is visiting friends.

Query: Was it pyæmia or anæmia of the brain that caused the dementia? Was there any connection between the muco-purulent deposit in the urine, and the formation of pus in the pus cavity?

J. E. Milner, Jr., M.D.
Comanche, Texas.

Book Reviews.

Lectures on Nervous Diseases. By Ambrose L. Ranney, A.M., M.D., Professor of the Anatomy and Physiology of the Nervous Diseases in the New York Post Graduate Medical School and Hospital. Philadelphia: F. A. Davis, 1888. Pp. 775. Price, $5.50.

This work as the title indicates, is mainly a compilation of a course of lectures, but they have been so elaborated for the purpose of publication that the book has rather the character of a distinct treatise. The author, however, does not purpose writing for only the specialist, the pathological anatomist, or the skilled histologist, but rather for the busy practitioner, for him who has not the time to devote to the more abstruse and recondite matters relating to a single aspect of disease, but only enough to employ in studying its purely practical signification. To this end we think the author has arranged his matter and chosen his illustrations most admirably. Of the latter there are one hundred and ninety-two, nearly all in colors, and all neatly finished with the exception of several showing the application of electricity, which are rather crude. The plates illustrating pathological changes and the nervous relationship of different facts are chiefly diagramatic, rendering the context more clear to him who is not especially skilled in this branch. We also commend the author's practice of giving macroscopic drawings of the appearance assumed by the body and by various parts, in consequence of different diseases, instead of filling the pages with microscopical illustrations of the different degenerations, and alterations in ganglia, nerve roots and nerve terminations. The figures are in harmony with the text.

The first section is devoted to "Anatomical, Physiological, and Pathological Deductions Respecting the Nerve Centers of Man." In this section diagrams are given showing the relationship between the various components of the nerve organism, if we may so call it; and also the parts affected in the various diseases, beginning at the cortex and going down.

Part second: "Clinical Examination of Patients Affected with Nervous Diseases."

This section seems to us to be exceptionally valuable. It is so clear, that it leaves little to be desired. With regard to the difficulty of making a diagnosis in nervous diseases the author says: "The majority of practitioners apparently join in the feeling (which happily conduces largely to the benefit of specialists in neurology) that nervous anatomy and physiology is too complex a study for them to master; and that they must be therefore given over to those who are devoting themselves particularly to the department of nervous diseases. While this is true in part, I believe that it is not only possible, but comparatively easy, for any medical practitioner who is willing to make the necessary effort, to grasp certain general principles which are applicable to the examination of cases afflicted with nervous diseases. The subject of arriving at a diagnosis is then discussed under three heads, each thoroughly treated:

1. The clinical history of the patient, and how to record the chief symptoms of each case.

2. The symptoms revealed to the physician by his sense of sight.

3. The symptoms revealed to the physician by instruments of various kinds and other tests.

The third section treats of "Diseases of the Brain and its Envelopes." The different diseases are here taken up in order with their morbid anatomy, etiology, symptoms, diagnosis, prognosis and treatment.

A number of diseases likely to be confounded are carefully distinguished by separate and elaborate differential diagnosis.

Section four: Diseases of the Spinal Cord and its Envelopes.

Section five: Functional Nervous Diseases. We notice that the author lays great stress on reflex irritation from strain on imperfect eyes as a potent factor in the causation of many cases of functional nervous diseases; even going so far as to say with regard to migraine: "For many years I have taught in my lectures that I had yet to meet a case of typical migraine in which an examination of the eyes or the eye-muscles would not show the existence of a marked error. All observations to date confirm me in this view. Latent hyperopia is an extremely common cause of reflex disturbance in these cases; and esophoria or hyperphoria are not infrequently found."

In the sixth section are considered the Toxic and Unclassified Nervous Diseases," such as hydrophobia, multiple neuritis, chronic lead poisoning, arsenic paralysis, and the like.

The final section is devoted to "Electricity in Medicine." The author devotes over a hundred pages to this subject, first describing the different kinds of electricity, next the mode of construction of the different apparatus, and finally giving ample directions for the proper application of the several kinds; and, in fact, full information on all points connected with electro-therapeutics. A number of diagrams showing the various motor points, and a good index complete the contents of the volume.

Dr. Ranney may congratulate himself by the thought that in this excellent work he has added something valuable and lasting to the bibliography of nervous diseases.

THE ETIOLOGY, DIAGNOSIS, AND THERAPY OF TUBERCULOSIS. By PROF. DR. H. VON ZIEMSSEN. Series III, Physicians' Leisure Library. Detroit: George S. Davis. Price, 25 cents.

This is an attractive looking, neatly printed little paper bound volume of 118 pages, being in substance a course of lectures delivered by the author. The book is divided into three parts in accordance with the title; part first treating of the etiology, in which, by the way, we notice that von Ziemssen believes in the hereditary transmission of tuberculosis; part second, diagnosis; and third, treatment. He considers fresh air of the greatest importance both in prophylaxis and in treatment, citing the fact that 50 per cent. of the deaths of nuns are from tuberculosis, and that from three to ten times as many prisoners die of the same disease, relatively speaking, as do ordinary people.

Gleanings.

LUYS reports a case of paralysis agitans in which considerable amelioration followed treatment by hypnotism, with rotary mirrors.

M. BOISSEAU DU ROCHER has treated many patients affected with constipation in the following manner: He prescribed two spoonfuls of effervescent citrate [?] before each meal; then he galvanizes the intestine two hours after breakfast, terminating by a general static electric *séance*. Ten *séances* effect a cure.—*La France Méd.*

A. R. SMART, M.D. (*Toledo Med. and Surg. Reporter*), advocates igni-puncture for internal hemorrhoids. After forcibly dilating the sphincters, the base of each tumor is perforated one or more times by a wire of the size of a knitting needle, heated to a dull red. The patient is put to bed for from five to seven days after the operation, and on the second the bowels are opened with a gentle enema. In four or five weeks hardly a trace of the tumors will be found; no loss of tissue and subsequent contraction; only small indurations, which will subsequently disappear.

ATHLETES AND ATHLETICS.—Irving Ross, M.D. (*Jour. Am. Med. Assoc.*), holds that the popular opinion as to the danger to health and life connected with great muscular exertions is in the main fallacious. He has never found a case of hernia caused by over-exertion, though he has known many hundreds of athletes. He maintains that they are not more subject to aneurism and heart disease than other people; that instead of having their lives shortened they are, as a rule, a rather long lived class, citing a number of noted examples in proof; that where disease or death does come early it can generally be shown to be due to free indulgence of gross appetites and indulgences; in short, "that all the manly sports should be encouraged and fostered with a view to promote qualities that intimately concern not only the happiness and usefulness of individual life, but also the good of society, and the future of the human race."

MANIA AND MELANCHOLIA FOLLOWING GYNECOLOGICAL OPERATIONS.—Dr. T. G. Thomas reported in a paper before the New York Academy of Medicine six instances in which acute mania or melancholia followed these operations: removal of ovaries, one; of breast, two; of abdominal tumor, one; perineorrhaphy, two. The last two cases died within three weeks after the operation, one in acute mania, the other in acute melancholia; of the two breast cases, one died within two weeks in acute melancholia, the other is still violently insane; the case of abdominal tumor died in eight days, maniacal; and the patient whose ovaries were removed recovered entirely, though after a period of confinement in an insane asylum In four out of these six cases there was evidence of eccentricity before the operation.

Position of the Vulva in Negroes.—Weiss (*Revista de Cienc. Med.*) states that extended observations show the vulva of negro women to be about two centimetres farther back than that of Europeans. The low position of the vulva is very rarely seen in white women; while in negroes he did not find any instance in which the vulva occupied the same position as in whites. The most important result is that with negroes the period of perineal distension during parturition is much shorter and less painful than with their white sisters.

A New Treatment of Epidemic Diphtheria.—Dr. Arthur Hennig reports excellent results in the treatment of diphtheria by the use of lime water as a gargle, taking a swallow of two and a half to five drachms every quarter or half hour, according to the severity of the case, and by the local use of the ice bladder.

If the patient cannot gargle, he gives lime water in sufficient quantity internally; or, having the patient bend his head backwards, pours lime water in his mouth and then shakes his head in all directions. This procedure is to be continued until the spreading of the false membrane can be stopped and it can be seen to loosen.

When a child cannot gargle, and will not take the lime water internally, he used a steam atomizer (Richardson's), of such construction that it can be used in inspiration only; if used in expiration the carbonate of lime might be precipitated.

He gave as much as three quarts of lime water a day during the disease without bad result; but to prevent the lips from becoming sore, he rubbed them several times a day with vaseline.

Sometimes he ordered chlorate of potash internally, but never as a gargle, and always on a full stomach. When the fever is very high he gives anti-thermic remedies, such as antipyrin and antifebrin.

The ice he puts in the œsophagus of an ox or a cow, about ten to twelve inches long, which will reach from one ear to the other. The ice bag, made up in the above manner, is wrapped in a cloth and put about the neck of the patient. The patient under this mode of treatment not only feels comfortable, but the body temperature also falls considerably. The pulse becomes more frequent, swallowing easier, and the exudation less. The application of the ice is persisted in until the patient complains of being cold, or of burning in the throat, which generally is on the sixth or seventh day. By this time the membranes are loose and thrown off in shreds, and the new formation of epithelium started.

Among ten hundred and fifty-four cases treated during ten years by this antiphlogistic method, not a single instance of a bad result, on account of the treatment, was noticed.

As a diet, milk is the best, then beef-tea; meat which is easy to digest may be given sometimes for a change.

As soon as the patient feels well enough, he lets him get up and walk about, especially if a child, and such cases are generally of shorter duration and without sequelæ.

The chronic form of epidemic diphtheria was also treated by this method with very good results, and he thinks that lime water cannot be displaced in efficacy by any other drug in the treatment of epidemic diphtheria.—*Deutsche-Medizinal Zeitung.*

Hysteria.—Janet (*La France Méd.*) gives the following singular case: The patient had a neurotic history, embracing chorea, anæsthesia, hemichorea and hemianæsthesia, and hysteric crises, alternating with paroxysms of somnolence. At twenty years of age she was seized with anorexia, which increased to an absolute dysphagia. The sight of a cup of water brought on violent efforts at vomiting, lasting many minutes. For fifteen months she was nourished by the sound. but as nearly all the food thus taken was soon vomited, she became quite feeble. The urine had to be drawn, she became paralytic, and her emaciation was extreme. She proved an easy subject for hypnotism, and was readily thrown into a somnambulistic state, in which the dysphagia disappeared completely. She was thus fed daily with two full meals of chicken, soup, eggs, and beer. This was kept up for eighteen months, by which time a decided change had taken place for the better; the paralysis disappeared and she grew plumper. But while she appeared to be cured, it was only while hypnotized; when awake she could not swallow a cup of water.

She was then awakened by degrees during the repast, and induced to eat each day while in a state more nearly akin to wakefulness. In three months she was able to eat while fully awake. Four months later the symptoms returned in their original severity. The same means were employed, but instead of hypnotizing her for each meal, she was left in that state for an indefinite period. It was five months before she could quit the hospital, and even then she was unable to eat while awake. She was sent out still in a state of somnambulism.

The inconvenience of this method is that she has no recollection when awake of what has passed during her trance. When awakened, she takes up the consciousness of the day and hour when she last fell asleep. In fact, in this woman there has been created a double existence.

The Identity of Erysipelas and Acute Lymphangitis.—MM. Verneuil and Clado, after making some careful investigations, form the following conclusions:

1. Erysipelas and lymphangitis are only two forms of one and the same contagious, infectious, and parasitic disease.

2. Their agent is a special microbe, easy to recognize and to isolate, to cultivate and to inoculate in animals.

3. This microbe, discovered and described in erysipelas alone, is found in lymphangitis with its characteristics and properties complete.

4. The absolute identity of both cause and nature of the two diseases is established definitely, although considered by many authors as distinct.—*La France Médicale.*

Electricity in Diseases of the Brain and Vaso-molor System.—L. C. Gray, M.D., in *New York Medical Journal*, divides diseases of the brain with respect to electrical treatment into the insanities and the gross cerebral lesions. Subacute mania, melancholia, the insanity of doubt, and those other various morbid fears and fancies—functional insanities, can all usually be benefited by electricity, but only in the period of convalescence. Of these meloncholia will best respond to treatment, mania next, while the benefit in the insanity of doubt and the functional insanities will vary greatly. Electricity is of no use in brain tumors, in meningitis of trumatic or epidemic or aural origin, or in facial hemiatrophy. Along with other treatment it is serviceable in intra-cranial syphilis, in the early stage of headache and insomnia. Tic douloureaux is uncertain in its response. The form of electricity used is important. Static electricity is of no value, and the Holtz machine is simply an imposing toy that may have a temporary effect on impressible people of hypochondriacal or hysterical tendencies. The insanities, as a rule, require treatment only to the intra-cranial contents, and that is best done by the galvanic current. The gross cerebral diseases produce two great classes of symptoms, those that are entirely cerebral and those that are both cerebral and peripheral. In the former, galvanism to the intra-cranial contents, and in the latter, galvanism to intra-cranial contents whilst faradization of affected peripheral structures. Galvanism is applied by putting one electrode upon the nape of the neck, and the other on the forehead. Begin with very light current and gently increase to one or rarely to than two milliamperes. Three minutes is long enough for the first sitting. Gradually decrease strength of current, then remove electrodes. In spite of all that has been said, the author after sixteen years' experience has not been able to notice any therapeutic difference between the poles; if one pole does not agree, he tries the other; if that does not he stops the electricity.

Phenacetin. — Dr. James G. Kiernan, M.D., of Dunning, Ill., speaks thus of Phenacetin in the *Medical Standard* for April: "While it is quite as powerful as methozin and acetanilid, it does not cause the pain in the stomach, nor the scarlatiniform rash of the former; nor does it give rise to the cyanosis of the latter, however prolonged may be its administration, and though Dujardin-Beaumetz has given it for months, in doses of 1–2 grammes per diem, there have never been observed bad effects. He has used it in every form of pain (neuralgiæ, migraine, rheumatic pains, muscular rheumatism, acute articular rheumatism, the lightning pains of tabes, etc.,) with the best results. Further, in cases of hysteria, and of hysterical or neurataxic pains, phenacetin has seemed to produce better effects than bromide. It calms the excitability of the nervous system, and in some obstinate cases of nervous insomnia it procured sleep. Phenacetin seems not only an analgesic but a hypnotic.

I have tried phenacetin (para-acet-phenetidin) in ten cases of migraine. Of these, three were epileptiform, arising from coarse brain disease, tumors, cerebral abscesses, etc. Here the drug given in five-grain doses four times daily, had excellent effects as regards the pain. The migraine was, however, replaced by fits of temper (the patients were children).

In the other cases there were temporarily beneficial effects. In two of these cases (the patients had a neurotic ancestry), a scarlatiniform rash made its appearance twice on the use of five-grain doses. It desquamated rapidly, and was noticed only after the first two doses. In trifacial neuralgia, phenacetin was often of value, when supplemented by constitutional treatment, where diathetic conditions were present. Constitutional treatment without the phenacetin did not give good results.

In a few cases of insomnia, resulting from simple exhaustion, phenacetin in ten-grain doses proved to be a valuable hypnotic. It failed in the excited states of mania and melancholia. In a few cases of agitated dementia, there was a temporarily beneficial hypnotic effect. The fulgurant pains of locomotor ataxia were temporarily relieved. In two cases of fever, cyanosis and excessive sweating were observed to result from five-grain doses.

In my judgment the scarlatiniform rash, cyanosis and excessive sweating must result in predisposed cases from any hypnotic or antipyretic which exercises its action through the nervous system. To be efficient, drugs must exercise powerful action on certain centers, and in defective nervous systems, these drugs must produce effects which take the line of the least resistance."

The Gynecic Element in Psychiatry.—C. A. Reed, M.D., in *Buffalo Medical and Surgical Journal*, holds that mental disturbance and actual insanity in women are much more frequently due to some lesion of the genital apparatus than is generally supposed. He believes that there are to-day, in our asylums, many female patients confined, whose condition under proper treatment for the local lesion might be greatly ameliorated or the patients entirely cured. In support of his views he cites a number of cases in his own practice in which insanity or melancholia had developed on account of some menstrual trouble, pelvic tumor, inflammation, or the like, but had disappeared upon curing the local lesion.

The cases he mentions are these: Pubescent mania from delayed menstruation—recovery; melancholia from pelvic abscess—operation—cure; aphasia from cervical stenosis—operation—cure; hystero-epileptic insanity from diseased uterine appendages—laparotomy—cure; puerperal insanity—laparotomy—drainage—recovery. Under the aphasia case the author remarks: "Here was a case in which, viewed entirely from a psycho-neurological standpoint, the lesion would have been located according to Broca, in the third left frontal convolution; or according to Meynert, in the Island of Reil; but viewed from the gynæcological standpoint, the essential lesion so far as the aphasia was concerned, actually existed in the submucous ganglia, which, according to Frankenhäuser, comprise the termini of the uterine nerves."

Medical News and Miscellany.

GERMANY is over-crowded with doctors.

YELLOW FEVER is epidemic at Truxillo, Peru.

DR. B. H. DIEHL has removed to 2151 Park Avenue.

DR. P. S. DONNELLAN has removed to 1028 Arch Street.

DR. J. A. KRUG has located at 2437 North Fifth Street, Philadelphia.

CHILI horses have the epizoötic. This makes it chilly for surburban dwellers who rely on street cars.

SMALLPOX and scarlatina make life unsafe in the ancient city of Siena, as well as in many other Italian towns.

SYDNEY J. ARMSTRONG, the surgeon of the Inman Line Steamer City of Paris, committed suicide. He had been drinking.

DURING the past year the Pennsylvania Hospital treated 2363 cases in its wards, 4409 accident cases, and 7616 out-patients.

DRS. CARL FRESE and H. R. Wharton are the Physicians to the new Children's Hospital at the Mary J. Drexel Home.

ON page 17 of the TIMES AND REGISTER, May 4, the name should have been John G. Meachem. Another argument in favor of the typewriter.

ONE thousand Italians landed at Rio de Janeiro and stepped off their vessel into an epidemic of yellow fever. In eight days more than one-half were dead.

A LOUISVILLE physician recommends the douching of children's upper air-passages with creolin solution as a prophylactic during the prevalence of diphtheria.

IN St. Louis, a doctor who was called to see a sick child found a quack at the bedside, whereupon the irate physician kicked the pretender down stairs. The child died.

A CHICAGO doctor says 50 per cent. of the men of that town are crazy, because they get out of their woolens and into pneumonia during this merry month of May.

THE treatment of mental diseases by colors is revived. Melancholy requires red; acute mania, blue. The young love yellow, the color most conducive to growth; while old age prefers the warm red ray.

THE Ohio State Medical Society holds its Forty-fourth annual meeting at Youngstown, on May 22 to 24. Among the principal attractions are papers by A. R. Baker, H. J. Herrick, A. B. Carpenter, H. S. Upson, R. A. Vance, and B. L. Milliken of Cleveland; S. D, Ayres, C. W. Tangeman, A. B. Thrasher, M. Thorner, F. Forchheimer and J. F. Whittaker of Cincinnati; D. T. Gilliam, S. Loving, A. W. Sharp and S. S. Stein of Columbus, and a number of prominent men from Toledo, Zanesville, Akron and other Ohio towns.

NOTES FROM L'UNION MED. DU CANADA.

WHEN patients resist the action of atropine, substitute duboisine.—*Foucher.*

MENTAL distress, especially when due to love, is a powerful cause of chlorosis in young girls.—*Laramée.*

THE angularity of the features is very remarkable in persons suffering from cancer, even while as yet latent.—*Laramée.*

IN chronic parenohymatous nephritis the lumbar pains are generally more intense than in other chronic nephritic inflammations.—*Laramée.*

BEWARE of eserine in certain affections of the cornea complicated with iritis; complete adhesion of the sphincter iridis may result from it.—*Foucher.*

LANPHEAR (*Med. Index*), gives what is the usual final word in regard to remedies for pertussis. He finds antipyrin in certain cases efficient, and in others it has no appreciable effect.

TOBACCO AGAIN.—It is said that ten out of twenty candidates for cadetship at West Point were recently rejected on account of tobacco heart brought on by cigarette smoking.—*People's Health Journal.*

DR. THOMAS FEATHERSTONHAUGH gives a list of sixty-two different ways in which the word pterygium was misspelled by physicians. How many could he have collected if he had taken his own name as the test?

SHRADY has been interviewed again, and now gives us the important news that women meet death more bravely than men.

But, then, women have so much less reason to fear death, their chances in the hereafter being considerably better.

DR. BRYCE, editor and proprietor of the *Southern Clinic*, favored us with a call recently. Dr. Bryce is a typical Virginian, both in his appearance and in the manly way in which he lifts up his voice for the right; even if in doing so he is compelled to disapprove of the acts of his friends.

THE Griffin (Ga.), *News* is responsible for the story of a man who got a cut hand inoculated with cucumber juice and turned into a mass of cucumbers. Mrs. Credulous wonders why the regular physicians never unearth any of these wonderful cases, and she attributes it to their hide-bound dispositions.

Items of Interest tells of a girl, probably from Weighback, who could not be persuaded to enter the dentist's chair until she had received the most satisfactory answers to her inquiries as to how one was placed in the chair, and how the positions of the patient and the chair were changed after the patient was in it. The explanation satisfied her as far as lower teeth were concerned, "but," said she, "the most of my teeth that need filling are upper ones, and how do you fix the chair to fill them?" It afterwards turned out that a mischievous brother had told her that in order to fill upper teeth it was necessary for the dentist to reverse the chair so as to stand the patient on his head.

THE Attakapas Pharmaceutical Association, at Iberia, La., memorialized the Louisiana State Pharmaceutical Association, setting forth the inefficiency of the so-called Pharmacy law in securing to the people of the state the immunity from peril, that they are entitled to, from the indiscriminate sale and handling, by unqualified persons, of drugs, medicines and poisons as now permitted.

THE Press Bureau of the Chambers Street Hospital, New York, is one of the best organized in the country. From the St. Louis *Globe-Democrat* we learn that a man was brought there with both arms and both legs broken, one of the latter in three places, and internal injuries besides. One arm was amputated at the shoulder and one leg at the hip-joint. The remainder of the man bids fair to recover.

WE notice that Mr. William Torrey Grant, son of Dr. Grant Bey, of Cairo, carried off first-class honors in practical anatomy and second-class honors in theoretical anatomy, in the examination of the University of Edinburgh. It is a well-known fact that distinguished men rarely transmit their talents to posterity; but young Dr. Grant evidently does not propose to be known merely as "the son of his father."

ELECTRICITY FOR SNAKES.—A report comes by way of Germany, that a novel use of electricity has been made in India, for the prevention of the intrusion of snakes into dwellings. Before all the doors and around the house two wires are laid, connected with an induction apparatus. Should a snake attempt to crawl over the wires, he receives a shock of electricity, which either kills or frightens him into hasty retreat.—*Am. Analyst.*

SOFT WORDS.—The New York *World* says that twelve different albums are offered as prizes for smoking cigarettes, and that many a boy under twelve is striving for the entire collection, which would necessitate the consumption of nearly 12,000 cigarettes. All these Satanic influences at work to ruin our boys should spur every parent to redoubled efforts for their salvation.—*Union Signal.*

A FEARFUL RESPONSIBILITY.—In view of the repeatedly demonstrated fact that the death-rate, under homœopathic treatment, in all diseases, is from 10 to 60 per cent. less than under allopathic treatment, the man who enters upon the practice of medicine without practical knowledge of homœopathy takes upon himself the fearful responsibility of unnecessarily sacrificing a large percentage of the lives of those who die under his treatment.—*People's Health Journal*, (Homœopathic).

LEONARD, of Detroit, started the idea of publishing the names of the frauds who obtain credit from medical journals for advertising and then decline to pay their bills, with an impudent, "What are you going to do about it?" The law is a tedious, troublesome, and expensive remedy, and these men know it. But there is another method which they dread, and that is *publicity*. Drs. Leonard and Daniel have rendered medical journalism and honest advertisers a service by exposing these persons.

A DANGEROUS PRESCRIPTION.—A druggist in Minnesota asks the *Am. Drug Clerk's Journal* how the following precription could be prepared:

℞.—Potassii Permangan . . . . . ʒss.
Hydrarg. Chlor. Corr. . . . . gr. xv.
Glycerini . . . . . fʒij.

He tried dissolving, and that failing, next triturated them in a mortar and attempted to dissolve by heat, but always got a precipitate. The editor remarks that it was no fault of the drug clerk's he escaped alive, and that the prescription should have been refused.

Army, Navy & Marine Hospital Service.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service for the four weeks ended May 11, 1889.

PURVIANCE, GEORGE, Surgeon. Detailed as chairman of Board for the physical examination of candidates for appointment as cadets, Revenue Marine Service, May 3, 1889. Detailed as chairman of Board for the physical examination of officers, Revenue Marine Service, May 11, 1889.

IRWIN, FAIRFAX, Surgeon. To proceed to Bath, Wiscasset. Rockland, Belfast, Bangor, Ellsworth, Machias, and Eastport, Maine, as Inspector, April 22, 1889.

MEAD, F. W., Passed Assistant Surgeon. Detailed as recorder of Board for the physical examination of candidates for appointment as cadets, Revenue Marine Service. May 3, 1889. Detailed as recorder of Board for the physical examination of officers, Revenue Marine Service, May 11, 1889.

WHEELER, W. A., Passed Assistant-Surgeon. Granted leave of absence for thirty days, April 16, 1889.

BRATTON, W. D., Passed Assistant-Surgeon. Relived from duty at San Francisco, Cal., to assume charge of the Service at Portland, Oregon, May 8, 1889.

MAGRUDER, G. M., Assistant-Surgeon. To proceed to Baltimore, Md., for duty, May 8, 1889.

PERRY, T. B., Assistant-Surgeon. When relieved at Portland, Oreg., to proceed to San Francisco, Cal., and await orders, May 8, 1889.

To report to the Commanding officer, Revenue Steamer "Rush" for special duty May 11, 1889,

CONDICT, A. W., Assistant-Surgeon. When relieved from duty at Boston, Mass., to await orders, May 8, 1889.

To report to the Commanding officer, Revenue Steamer "Chase" for special duty, May 11, 1889.

HUSSEY, S. H., Assistant-Surgeon. When relieved from duty at Baltimore, Md., to proceed to Boston, Mass., for duty May 8, 1889.

GEDDINGS, H. D., Assistant-Surgeon. To proceed to Baltimore, Md., for temporary duty, May 8, 1889.

Changes in the Medical Corps of the U. S. Navy for the week ending May 11, 1889.

BEARDSLEY, GROVE S., Medical Inspector. Detached from the "Brooklyn," proceed home and wait orders.

LOVERING, P. A., Passed Assistant-Surgeon. Detached from the "Brooklyn," proceed home and wait orders.

NORTON, OLIVER D., Assistant-Surgeon. Detached from the "Brooklyn," proceed home and wait orders.

HAWKE, J. H., Surgeon. Detached from the "Essex," proceed home and wait orders.

STOKES, C. F., Assistant-Surgeon. Detached from the "Minnesota," and to the "Iroquois."

BRANSFORD, JOHN F., Surgeon. Orders to the "Iroquois" revoked. Resignation accepted to take effect May 4, 1890, with leave of absence granted to that date, with permission to leave the United States.

DIGITAL DIVULSION OF THE PYLORUS FOR CICATRICIAL STENOSIS.

(Read before the American Surgical Association, Washington, D. C., May, 1889.)

BY J. M. BARTON, A.M., M.D.,

Surgeon to the Jefferson Medical College Hospital, Philadelphia, Pa.

DIGITAL divulsion of the pylorus for cicatricial stenosis as first performed by Prof. Loreta of Bologna, Italy, in 1882, has scarcely received the attention which I think it deserves anywhere except in Italy.

The mortality from the twenty-five operations, which I have succeeded in collecting, is not great when we consider that every successful case is a patient rescued from certain and by no means distant death, and this mortality is already decreasing. When searching the journals for records of such operations, I found the reports of the presentation of many specimens of cicatricial stenosis of the pylorus to various pathological societies, showing that the cases in which this operation would be of service are not so very rare.

My own experience has been limited to two operations. Even the first, though it proved fatal on the fourth day encouraged me to operate again, as I was fully satisfied that had it been performed earlier, when the patient was stronger, there was no reason why it should not have been successful. My second case has the following history:

Mrs. Y., aged forty-eight years, a patient of Dr. Adams, of Vineland, N. J., was first seen by me at her home near Vineland, in December, 1888. For convenience of study and operation I admitted her to Jefferson College Hospital in January, 1889.

During 1884, 1885 and 1886, she suffered from gastric ulcer. She had pain and vomiting immediately after eating, the vomiting occurring as often as six times in the twenty-four hours, she had lost greatly in weight and had two severe hemorrhages.

In 1887 all the symptoms left her and for the greater part of the year she enjoyed excellent health, weighing in January, 1888, one hundred and forty-three pounds, which was more than she had ever weighed in all her life. During 1888, she became very ill, with symptoms of pyloric obstruction and lost flesh rapidly, weighing after her admission to the hospital in January, 1889, only ninety-three and a half pounds. She then vomited but once in twenty-four or forty-eight hours; this occurred when she laid down at night and was not accompanied by nausea. It was usually from one and a half to two quarts in quantity and measured nearly, and sometimes quite, as much as all the nourishment taken since the preceding act of vomiting twenty-four hours before, many articles taken during the day could be recognized, indeed she stated that she had occasionally been able to recognize articles eaten as long as two weeks before.

As she took her meals she felt that her stomach was becoming more and more distended and when she

laid down at night gravity brought the contents of her stomach into her throat and they were then vomited.

Her bowels were obstinately constipated, acting only once in twelve or fourteen days, and then only after frequently repeated large injections; purgatives administered by the mouth producing no effect.

She had lately been able, occasionally, to feel a small tumor about the size of a hazel nut, two inches to the right of the umbilicus and situated quite deeply.

Her stomach was greatly enlarged; distended by the carbonic acid gas developed from half of a soda powder, it reached as low as the umbilicus, and as far as the small tumor, though we could not say that the tumor was connected with the stomach.

The vomited matters separated themselves into the usual three layers, the middle one being quite clear. They were nearly free from undigested food and not offensive; free hydrochloric acid though searched for was not found.

The operation was performed in the presence of the class of Jefferson Medical College on February 16, 1889. The abdomen of the patient had been prepared the day before, the mercurial dressings being still on when she was brought into the amphitheatre for operation. Her stomach had been washed out on the morning of the operation with a solution of bi-borate of soda; this had been repeated until the fluid returned quite clear. Chloroform was used as the anæsthetic in preference to ether as being less apt to be followed by vomiting.

The hands and instruments having been prepared with antiseptic solutions I made a median incision through the skin about four inches long, terminating at the umbilicus; the peritoneal incision was, however, only three inches in length. There was but little bleeding and it was readily controlled by clamp forceps.

The dilated stomach was found directly beneath the incision. The juncture of stomach and duodenum, even from the outside, was markedly contracted and irregular on its surface. There were no adhesions and no tumor was there. The tumor was found to be a hard scybalous mass in the ascending colon, which also contained quite a number of smaller masses of hardened fæces.

As the wall of the stomach three inches from the pylorus felt quite healthy, I folded it transversely, midway between the greater and lesser curvatures, and with a pair of sharp scissors made an incision between one and a half and two inches in length. There was no bleeding requiring any attention.

I introduced my index finger through this incision, and felt the pylorus contracted to about the size of a number ten French catheter; its margins were quite hard and fibrous. As the finger would not enter, the blades of a small uterine dilator were passed through the wound in the stomach, and guided by the finger, were introduced into the contracted pylorus, which was then readily dilated until it admitted the index finger; with the aid of a pair of œsophageal forceps it was still further dilated until both the index and middle fingers were admitted; the two fingers were then separated about half an inch, when I ceased, feeling that further effort would probably rupture the mucous membrane. This dilatation gave a circumferance to the pylorus of four and a half inches.

The mucous membrane of the wound in the stomach was brought together by a continuous silk suture and the serous coat by a continuous Lembert suture, also of fine silk, carried in an ordinary sewing needle; this suture was introduced deeply into the muscular coat in order to obtain a firm hold; even then it tore out at one or two points, requiring an interrupted suture to be used at those places.

When the finger was first introduced into the stomach it caused some retching, forcing most of the stomach out of the wound, where it was kept during the subsequent manipulations.

After the wound in the stomach was closed that organ was carefully sponged and restored to the abdominal cavity. The abdominal wound was then closed and dressed in the usual manner.

I am indebted to Dr. Callender, the resident physician, for the following history of the after treatment of the case, and also for the personal care and attention which he gave the patient.

Mrs. Y., operated upon February 16, 1889. She was nourished by the following enema given every six hours:

℞.—Valentine's meat juice	f℥ij.
Half of an egg	
Pepsin	gr.x.
Tr. opii	gtt.v.
Milk enough to make	℥ij.

She vomited about ℥iv of blood half an hour after the operation. She had no pain and was not greatly shocked.

February 17. Enema continued; she took ice in the mouth but did not swallow the water.

February 18. Same as the 17th.

February 19. Same as the 18th.

February 20. Enema was continued and at 1 P.M. f℥j of milk was given by the mouth; at 2, f℥iij, and at 4, 6, 8 and 10 f℥ss of milk.

February 21. The bowel became irritable and would not retain the nourishing injection. Therefore a ℥j of a weak solution of cocaine was thrown into the bowel seven or eight minutes before each enema which allayed the irritation. She took by the mouth f℥ss of milk every three hours during the night, and every two hours during the day.

February 22. The quantity of Valentine's meat juice was increased to f℥ss. The enemas were given but twice in the twenty-four hours. Six hours after each enema, a food suppository was inserted. By the mouth she took alternately f℥ij of milk and f℥ij of beef tea every two hours.

February 23. Bowel washed out by soap suds enema; as the suppositories were found unabsorbed their administration was discontinued. The nourishing enemas were given every six hours, composed as on the first day, except that each contained f℥ss of meat juice instead of f℥ij. They were preceded by cocaine as before.

The beef-tea and milk were given as yesterday.

February 24. The bowel becoming irritable the enemas were stopped.

Milk and beef-tea f℥ij every two hours.

Egg-nog morning and evening. Most of the stitches removed.

February 25. Bowels moved freely by soapsuds enema. ℥xx of milk, ℥xvj beef tea, ℥iv chicken-broth, and two egg-nogs were taken during the day. Rest of stitches removed.

February 26. Nourishment as yesterday.

February 27. Bowels moved by enema. Nourishment as yesterday, and a small piece of chicken.

February 28. ℥xvi milk, ℥xvj beef-tea; oyster broth, egg-nog.

March 1. Bowels moved by glycerin enema. Milk, beef tea, oyster broth, egg-nog, small quantity of chicken and a few oysters were given.

March 2. Continued.

March 3. Bowels moved by glycerin enema, milk toast, coffee and a poached egg for dinner. f℥xx. milk, ℥xx beef-tea, oyster and barley broth, egg-nog.

March 4 and 5. Same diet in same quantities.

March 6. Quantity of food slightly reduced, as an attack of indigestion was feared, though the patient would have preferred the larger amount. She was constantly hungry.

March 7. Was out of bed to-day for an hour and a half.

March 8. Chicken, rice, coffee and liquid nourishment.

March 10. Eggs, lamb chops, baked potatoes and liquid nourishment continued. Egg-nog stopped.

March 11. Bowels freely opened by citrate of magnesia; in most of her passages small, very hard, scybala were found. They had probably been in the colon before the operation.

March 14. Patient placed upon house diet, with some extras.

Her weight on February 8, before the operation, was 93½ pounds; on March 25, it was 110 pounds; on April 15, 118 pounds; on April 27, 122 pounds. She was able to leave the Hospital April 10.

At no time was her temperature over 99°, or under 98° F. She had no pain at any time, and required no anodynes.

I have succeeded in collecting twenty-five published operations, which I have included in the above list. Many of these are by Prof. Loreta. I had hoped to have obtained the results in all his cases, but Dr. Peruzzi, his chief-assistant, replies to a letter of inquiry, "that the Professor has performed in all about thirty operations, and that at least six more have been performed by other Italian surgeons, and they were all successful when the diagnosis was correct." This would make the total number of operations performed about forty-three.

The twenty-five operations included in my list were performed upon twenty-four patients, one patient having been operated upon twice, successfully, by Prof. Loreta. From the twenty-five operations there were fifteen recoveries and ten deaths; making a mortality rate of 40 per cent.

Two operations, both successful, were performed in England; five in America, with three deaths; but none in France or Germany, though in the journals of these two countries many of the Italian cases appear in full.

Three operations were attempted in Germany, one ending in resection, one in partial resection and partial dilatation,[1] while the third was completed by a successful plastic operation.[2]

In France, the pylorus was dilated for cancer, a fistulous orifice was left, through which it was kept dilated by a bougie introduced every third day, the patient died on the twelfth day.[3]

Of the ten deaths in the twenty-five operations included in my table, six were due to shock, two to hemorrhage, one to tetanus, and one to suppression of urine.

The large mortality from shock, from an abdominal section performed in from half an hour to an hour, is probably due to the fact that in this, as in most new surgical procedures, the operation is postponed too long.

The mortality is already decreasing; of the first twelve cases reported, six recovered and six died, while of the last twelve nine recovered and but three died.

This mortality can, perhaps, still be lessened by earlier diagnosis and operation, and by such methods of operation as are most quickly performed and accompanied by the minimum loss of blood.

[3] "Bertoye Lyons Med.," 86, Vol. 2, p. 96.

Diagnosis.—The diagnosis can be conveniently divided into two parts: (1) to determine the existence of pyloric obstruction, and (2) to differentiate between the obstruction caused by cancer and that caused by cicatricial stenosis.

But few of the reported cases have such a typical history as the one of my own, which I have just read; the co-existence of dyspeptic symptoms or of some still open ulcers complicating, the diagnosis in most of the cases.

From a study of these cases, I would regard as of little value some of the symptoms upon which much stress has been laid.

The material vomited in some cases consisted of partly digested food, in some it was wholly undigested and offensive, while in others it consisted of well elaborated chyme.

The character of this material indicates the health and physiological activity of the stomach, but throws but little light upon the condition of the pylorus.

In dilatation of the stomach due to mechanical obstruction, the glands of the stomach are not necessarily affected, and perfect digestion may go on.[1]

In some of the cases sarcinæ were present, but in many they were absent. The same may be said of starch granules, of needles of the fatty acids, of free hydrocloric acid, of the symptom of pain on percussion, of pain and burning on taking food, and of the other dyspeptic symptoms which usually have existed in most of these cases for many years before the symptoms of obstruction occurred.

The vomiting of blood is often quite a recent symptom,[2] and probably indicates the existence of some unhealed ulcers.

The vomiting is rarely typical, it often occurs four or five times a day, quite often immediately after taking food,[3] and some patients are unable to take any food whatever by the mouth.[4]

The following symptoms I would consider of value:

1. A greatly dilated stomach.

2. The vomiting of from one to two quarts of material at one time.

3. When in the matters vomited articles are recognized that have been taken many hours, days or weeks before. In one case two prune stones were found which had been swallowed two years before.[5]

4. When the act of vomiting is performed with great ease, without nausea and the appetite is good immediately after.

5. Obstinate constipation.

6. The non-effect of ordinary purgatives, as they do not pass the pylorus.

7. A preceding history of gastric ulcer of several years' duration and temporary improvement, followed by simple obstructive vomiting of well elaborated chyme many hours after taking food. This typical history occurred but twice among the twenty-four patients.

[5] "Raccog Med." '83, p. 147.

Where the symptoms are obscured by co-existing disease of the stomach great reliance may be placed upon the detection of a decidedly enlarged stomach, as this condition is very rare except from mechanical obstruction of the pylorus.[1] In one of the cases the stomach reached to within two inches of the symphysis pubis,[2] and in most of them it reached below the umbilicus.

This dilated condition of the stomach may be suspected when from one to two quarts of material are vomited at one time, and can be accurately determined by distending the stomach with carbonic acid gas, developed from bicarbonate of soda and tartaric acid introduced separately; or by pumping water in and out of the stomach and measuring it.

Medical treatment may relieve some of the complicating symptoms, and those left may then be typical of obstruction.

The obstruction may be due to the presence of a malignant growth, or to cicatricial stenosis. There are a few cases due to other causes, but they are very rare.[3]

The mere presence of a tumor is almost without value in making the differential diagnosis between cancer and stenosis. In the twenty-four reported cases a tumor was present in seven, absent in four, and not noted in thirteen.

Prof. Tyson has called attention to the fact that cancerous growths usually drag the pylorus several inches below its normal position.[4]

The tumor found in stricture of the pylorus is produced by the original ulcer penetrating the mucous membrane, causing peritoneal inflammation and adhesion to the omentum and to the surrounding structures; this would fasten the pyloric extremity of the stomach before the ulcer had healed, and of course, long before the contraction of the pylorus and the subsequent dilatation of the stomach took place.

We would, therefore, expect the non-malignant tumor to be higher in the abdomen than the malignant one.

A rapidly growing, well defined, nodular tumor, low down in the abdomen, is probably malignant. A poorly defined tumor, not increasing under observation, high up in the abdominal cavity, is probably non malignant.

The average duration of cancer of the pylorus according to Brinton, is one year. The maximum duration according to Bartholow, is three years. In the above table the average duration of stomach symptoms in the thirteen cases in which it is given is over eleven years.

In cancer bleeding is frequent, though rarely profuse; in ulcer it is much less frequent but is usually a decided hemorrhage when it does occur.

Fragments of a malignant growth may occasionally be found in the matters ejected from the stomach.

The history of a temporary improvement is against the disease being malignant.

The presence of hectic, of the cancerous cachexia,

[3] "Pepper's Syst. Med."

[4] "Phil. Path. Soc."

of secondary growths and of diarrhœa mark the latter stages of a malignant growth.

In the latter stages of cancer the obstruction is often removed by ulceration of the growth, obstructive vomiting ceases and diarrhœa occurs from the irritation caused by the discharge from the ulcerated surface. In the latter stages of ulcer the stenosis increases and the constipation is more obstinate.

The Abdominal Incision.—In all of the reported operations but two methods of opening the abdomen have been used; one by an incision running from one inch below the ensiform cartilage, to the extremity of the ninth rib on the right side, a distance of about six inches; the other being by an incision in the median line between the ensiform cartilage and umbilicus, and from three to six inches in length.

The first method was used by Loreta in his earlier cases, though he now uses the median exclusively; of the two the median is the better as there is much less bleeding and it takes much less time. In my last case though the incision through the skin was four inches in length, the peritoneum was only opened for three inches; this I found gave quite sufficient room. *The stomach wound* should be made far enough from the pylorus to be in healthy tissue; this may lessen the bleeding which in several of the cases was reported as terrific, requiring the use of T forceps and of ligatures. If some inches away from the pylorus it will be outside the zone of inflammation following the stretching. This distance will not interfere with the manipulations in the pylorus as the stomach walls are quite pliable.

Stretching the Pylorus.—Loreta states in the report of one of his cases that he placed his two index fingers in the pylorus and separated them three inches. Dr. Harris who translated this case for the *Medical News* regards this statement as a clerical error, but in the report of some subsequent cases Loreta repeats the statement.

In experimenting upon the recent cadaver I found that when I separated my fingers more than an inch, the mucous membrane ruptured.

Dr. McBurney, of New York, lost one of his cases from hemorrhage from a rupture of the mucous membrane produced while stretching the pylorus to a long diameter of three inches.

In my last case I introduced the index and middle fingers and separated them about half an inch. I felt that this was all the parts would bear. This gave a circumference of four and a half inches. None of the successful English or American cases have been dilated to any greater extent. One of these cases was still in good health nearly two years after the operation.

Closing the Stomach Wound.—In the twenty-five reported operations the stomach wound has been closed in every possible way; by Gely's suture, by the suture of Appolito, by interrupted Lembert suture, by continuous Lembert suture, by cat-gut, by silk, by sewing the mucous membrane with cat-gut and the peritoneum with silk, by sewing the mucous membrane with silk and the peritoneum with cat-gut and by various compound sutures; they all did well; the stiches did not give way in a single case, in none was there the slightest leakage, none suffered from peritonitis, and in none was the stomach wound the cause of death.

Peruzzi writes that Prof. Loreta has never had any trouble whatever from the stomach wound. Therefore, the most rapid of these methods would probably be the best, and I would suggest a continuous suture of cat-gut to the mucous membrane, and the suture of Appolito to the peritoneum, though I did not use this method in either of my cases.

Food after the Operation.—Among the reported cases food has been given as early as a few hours after the operation without injury,[1] and in one case nothing but ice was given by the mouth for seventeen days.[2] In my first case I gave food by the stomach on the second day owing to the exhausted condition of the patient. In my last case I delayed until the fourth day; though from the collected cases I see no reason why it should not be begun earlier. Peptonized milk, animal broths, diluted wines and the yelk of egg, would be best, depending upon the condition of the stomach previous to operation.

Rectal nourishment will be required until sufficient food can be given by the mouth.

Solid food has rarely been given before the tenth day and then sparingly.

Anæsthetic.—Chloroform if the heart's action is good would be better than ether, as it is much less apt to be followed by vomiting.

Permanency of Cure.—Recontraction of the cicatricial tissue and reproduction of the stenosis would naturally be feared, but Loreta in a letter to Holmes in January, 1885, nearly three years after his first operation, writes: "I have now operated upon six cases, they all have recovered and all remain well up to the present time."

Haggard performed his operation, March 7, 1886. In the *British Medical Journal*, of March 19, 1888, over two years after, his case is reported as "still perfectly well, no vomiting, dilatation of stomach less and she has recently married."

Peruzzi, in his letter to me of March 22, 1889, states that he knows of only one relapse among the thirty cases upon which Prof. Loreto has operated, this patient was re-operated upon, recovered and remained well. This case is probably No. 22 on my list.

In one of the fatal cases included in my list the obstruction was valvular, due to irregular contraction of the walls of the stomach.[3] In another case, not included in the list, as the pylorus was not dilated, the valvular obstruction was caused by distortion produced by external adhesions, these were divided and the patient made a good recovery.[4]

In another case not included in the list, the operator recognized that he had badly ruptured the mucous membrane while stretching the pylorus. He immediately performed pylorectomy with recovery of the patient.[5]

In another case, the obstruction was caused by the

adherent pancreas, the cause of the adhesion was found to be a healed ulcer starting in the posterior wall of the stomach and penetrating the pancreas.

In this case, an incision about two inches in length was made from stomach to duodenum, passing through the pylorus. The two extremities of the wound were brought in contact and the wound sewn up at right angles to its position when made. When completed it was parallel to the long axis of the body. This patient recovered after a serious illness.[1]

HUNTING THE GERM OF YELLOW FEVER.

By FRANK S. BILLINGS.

(Director of the Patho-Biological Laboratory of the State University o Nebraska.)

[Continued from page 55.]

HENCE, knowing the abilities of the original investigators employed by the Government such evidence is of no value whatever.

Dr. Paul Gibier was sent by the French Government to study this disease during the late eruption in the Southern States and contributes a paper on the Yellow Fever, an Experimental Study on its Etiology,[1] which is absolutely worthless except as evidence of the absurd unfitness of the author for the work he was intrusted with.

In the first place he is inclined to attribute the black vomit in per-acute cases of the yellow fever to a pigment, secreted by a germ which he thinks specific because "its biological qualities are entirely in accord with the physiology of yellow fever itself, and in certain conditions it blackens the bodies it comes in contact with, so much so that some liquid cultures have the appearance of black vomit," though he immediately qualifies this remark by saying, "I am far from pretending, although it has been so claimed, the last character, no matter how suggestive it may be, is pathognomonic." Then he admits "it does not always appear," and Sternberg says,[2] "The bacillus of Gibier I have only isolated in three cases; I have never observed in my cultures the black vomit pigment which, according to Gibier is produced during the development of this bacillus and am at a loss to understand this discrepancy in our observations." If Gibier can be trusted and his bacillus does produce black pigment, then Sternberg cannot be correct in asserting that he has met the "bacillus of Gibier," for on such a simple question, one or the other must be correct, and the one who errs incompetent. Either the bacillus is melano-genetic or it is not.

On the other hand I agree with Sternberg when he says: "So far as the pigment in black vomit is concerned I have no doubt that it is of hæmic origin," and not only because of his evidence that red blood cells are present in the vomitus, but because exactly similar conditions may be seen in occasional cases of the Southern cattle plague even though the animals do not vomit, and occasionally in swine plague.

It would have been well had Gibier given us Americans a description of an organism to which he attributes so much importance as to claim, "I think I am right in saying that the presumption that this bacillus is the cause of yellow fever tends to become a certainty."

But he gives us no evidence whatever in support of such a statement. On the contrary all he has to say is directly opposed to any such conclusions. It has not even collateral evidence in its favor.

Gibier continues: "Besides, I must notice that in cases in which autopsy took place early after death the blood, liver, spleen and kidneys have been constantly found free from microbes." This is simply an assertion to be taken *cum grano salis*. It is no more than saying, with Sternberg, "I could not find them," or words to that effect.

But to go on with our French authority who says: "This fact strengthens the theory which I have supported, viz.: that yellow fever is an intestinal affection."

However, two objections may be presented which I must answer.

1. "How is it that the microbe, supposed to be pathogenic, is not found in every case after death, and if it has disappeared, how shall we explain the persistence and the aggravation of the accidents?"

2. "If the yellow fever is a disease the germ of which grows exclusively in the intestines, how shall we explain the albuminuria?"

Earlier in my remarks I have spoken of the lamentable pathological inability of these investigators as evinced by the total absence of any detailed microscopical description, and as further evidence in the same direction, I point to the second question proposed by Gibier:

What should cause the albuminuria but the same factors which cause this phenomenon in many cases of acute diseases of the character of the yellow fever (in fact every one of the septicæmiæ is accompanied by albuminuria)? What but the extreme fever and sequential disturbances of the circulation and parenchymatous changes in the kidneys in consequence thereof? The kidneys are also full of microörganisms in this disease, Gibier, Sternberg, *et. al.*, to the contrary.

Gibier is undoubtedly right when he says that "the yellow fever is an intestinal infection," but further than that I decline to follow him. Were the respiratory tract the way by which these germs gain access to the human organism, we should have received some intimation of pulmonary lesions, but as we have not, the only possible way of infection must be by the digestive tract. Exactly the same thing occurs in the Southern cattle plague, but here we are very much in advance of these observers for we have demonstrated, in all necessary ways, the presence of the specific germ in the intestinal contents as well as in the blood and organs. In fact, it will do these gentlemen no harm, and we advise it also to the United States Government, as yellow fever appears to be so far beyond their limited abilities at present, that they take a little practice in a disease where the way has been opened for them, and study the Southern cattle plague. After they have done that satisfactorily they

[1] "Heinke, Central. f. Chir." '87, p. 55.
[1] *Med. News, loc. cit.*
[2] *Med. News, loc. cit.*

may be able to do something with its twin sister—the yellow fever.

Any one who has had long experience in the experimental study of this class of diseases, caused by a member of the ovoid belted germs, but more particularly with such as the Southern cattle plague and yellow fever, in which infection invariably occur via the digestive tract, will be soon struck by the very great variation in the number of germs found coursing in the blood and present in the organs in different individuals. I think it can be taken to be almost a rule, that the more prolific the infection, the more rapid the multiplication of the germ within the intestine, the greater and more intense will be the irritation of its mucosa with consequent proliferation of the cells in its follicles and crypts, as well as the greater the amount of ptomaine produced, which, while causing the most acute and severe symptoms by its absorption and dispersion over the organism, is still marked by the few germs, comparatively, which find their way through such an intensely swollen mucosa into the circulation. I have demonstrated this fact by experimentation. The same results can be achieved by the continuous feeding of strongly saturated bouillon in which the germs have been killed, without one being present in the organization, (See my Swine Plague Report).

Examination of Pieces of Organs from Undoubted Cases of Yellow Fever.—As has been remarked elsewhere, no one acquainted with the literature of the yellow fever could possibly be long engaged in investigations upon the Southern cattle plague of the United States without being most forcibly struck with the many strong points of resemblance between the two diseases. Let me at once most positively assert that, *I do not now think, and never have thought, that the two diseases are identical—that they are one and the same disease*—though for some unknown reason several reviewers of the first edition of my work have fallen into such an idea. Notwithstanding the closest resemblance in diseases, and, as I now again assert, in the morphology of their microörganismal causes, still any likelihood of these diseases being etiologically identical is absolutely contradicted by the fact that one can and does occur in its appropriate species of animal life without the other occurring at the same time in the same locality. The absolute folly of placing any great weight upon the most exact morphological correspondences in etiological organisms having any evidence in identity-diagnosis, and even the closest biological resemblances, is most conclusively shown in comparisons between the swine-plague and a new disease I have lately discovered the germ of, the so-called "corn-stalk disease." Here we have two diseases, one occurring in cattle, the other in swine, the germs of which are so near alike that even the most expert mycologist would not dare say which was which on a microscopic examination, and which even have many strong points of resemblance in cultures, but fortunately, also, equally strong ones of differentiation; and yet practical experience has conclusively demonstrated that each disease is confined to its own species, and even experiment has demonstrated the impossibility of inoculating the corn-stalk disease in swine. In this case we have again as strong points of conformity in the lesions induced in swine plague and those in the corn-stalk disease in cattle as between the Southern cattle plague and yellow fever, and yet, as asserted, these diseases are in no way identical, though belonging to the same class—extra-organismal septicæmia, and caused by a member of the group of the ovoid belted germs.

The coincidences between the Southern cattle plague and the yellow fever incited so much interest that every endeavor has been taken to procure alcoholic material from "undoubted cases" of yellow fever, and considerable means spent in that direction. I even went so far as to offer my services to the United States Government to go to the infected districts in Florida the past summer and fall, but the authorities appear to have had such sincere regard for my life and value to the country in other directions that no answer has ever been received from them on the subject.

However, I was eventually successful in obtaining quite a supply of really reliable material. The first specimens were sent me from Baltimore by Dr. Geo. M. Sternberg, and arrived at my laboratory in December, 1887, and were noticed in the first edition of this report. They were preceded by a letter from Dr. Sternberg, in which he says: "The material sent you is from an undoubted case of yellow fever."

In his address on Hunting Yellow Fever Germs,[1] the same observer says: "In my researches by the method of staining thin sections hardened in alcohol I have encountered several different microörganisms, *but no one of these has been found in a series of cases.*

"One, the bacillus of Lacerda and Babes, I have found only in material brought from Dr. Lacerda's laboratory, in Brazil, and in two only out of nine cases represented by material from that source."

These are the only cases mentioned by Sternberg in which he found the organism named.

It is somewhat singular what trips specimens of this material have been sent upon. First, it went to Babes and Cornil, in Paris; then to Baltimore; again, to me in Nebraska, and again, I have sent pieces of it to Koch, Hueppe, and Baumgarten, in Germany, as well as to several American observers, as also, pieces from the six cases which I received later, to which allusion will soon be made. Although Dr. Lacerda primarily saw this organism the first intelligent description of it was given by Babes,[2] who says:

"The capillaries of the liver and kidneys contain large numbers of jointed filaments. With a Zeiss $\frac{1}{18}$ H. I. one discovers these filaments to be composed of elliptic, cylindrical granules, united in pairs, or forming small groups, in which they are united by a pale intermediate substance."

The material upon which the above examinations were made was sent to Babes by Dr. Lacerda, of Rio Janeiro.

At a subsequent period Babes examined other material, sent by another physician, from two patients, but received negative results, as he did with the liver

[1] *Loc. cit.*

[2] "Les Bacteries," Cornil-Babes, Paris, 1885, p. 448.

of a third which he examined in connection with Robert Koch. He did not think that his results were positive enough to warrant any conclusive opinion.

[To be continued.]

PREREQUISITES TO MARRIAGE AND LAWS TO ENFORCE THEM.

By E. L. DETWILER, M.D.,
HERNDON, VA.

I. SUITABLE AGE AND HEALTH.

IT would be hard, indeed, to dwell with much importance upon the age which persons should attain before they begin the consideration, in a serious manner, of that great question of this life, viz.: the joining together in wedlock. Regarding it in a lesser light by the masses has been the chief incentive which caused me to attempt to place it before the profession for its consideration.

As we take a retrospective view we cannot help but see, especially through the eyes of a physician, the lack of judgment displayed in persons entering into, or about entering, the relations referred to. That the effects are more baneful and terrible to the welfare of the human race than is any single disease, I think no well-informed person can doubt, and yet diseases have volumes written on their prevention, treatment, and laws to prevent their spread.

Physiologists teach us that perfect development is not attained before the age of twenty-five, or thereabouts, for up to that age the epiphyseal connections of the osseous system have not entirely undergone that ossific change so essential for the welfare of persons who are about to make that great change in life; especially is this true of the female, as the pelvic articulations up to that age would be more likely to suffer damage than they would after ossification had been completed, owing to the great strain to which the pelvis is subjected incident to child-bearing and labor. With the male the age is not of so much importance as regards his osseous and muscular systems. But common sense demands that he be fully as old as his wife, or older. Again, a woman should not be too old, since later in life the coccyx joints become strongly ossified, and labor for the first time in such a person would be likely to fracture the coccyx. The other extreme in the male is not so important, so long as he select a wife of the proper age for marrying.

Our next thought is of a fit physical condition, or health as a prerequisite to marriage. This is a matter which, in my judgment, is of the greatest importance to a couple about to enter the marriage contract. And I think that it is not agitated enough, for comparatively no precautions are taken to prevent the great and lasting cycle of hereditary disease entailed upon the innocent offspring of unions where this matter has not been considered. For example, a person strongly predisposed to tuberculosis should, under no circumstances, marry, as he, or she, would probably be instrumental in bringing into the world weak, sickly, frail, puny human beings, probably destined to a premature grave, or else to drag out a miserable existence, a burden to themselves and all others, probably in turn becoming parents of families whose physical condition, in all probability, would be worse than their progenitors. And we might name many other diseases and conditions fully as awful in their effects upon the unfortunate child as the one which we have cited. We shall mention but two, however: struma, in its several forms, and the venereal disease. The latter, I think, cannot be measured in its vast production of misery, sin, and suffering. Now, I ask the question, could not something be done to prevent it, in a measure? Has a person any more right, legally, to bring a child into the world maimed, by disease, for life, than he has coolly and deliberately to injure one that has already been born? I think not. I can see no difference, and if any, it is in favor of the latter, as a broken bone, a striped or bruised body, would likely soon be repaired by the vitality existing in a healthy child. But not so with the unfortunate inheriting disease of some sort. Would the intelligent stock raiser leave the care and perfection of his animals to the fancies and lusts of their natures, we could very soon see the effect of it upon the herd. The handsome swine would rapidly degenerate into the more common breeds, and the spirited steed into the sluggish farm horse. But if they are turned out and given perfect freedom, the stronger males will always predominate, and either kill or drive away the weaker ones, and the result is that wild herds improve, as a rule, thus proving that the union of the more healthy and strong in the animals tend to improve their condition. If so in the lower animals, why isn't it true of the human race? We might dwell upon this matter at greater length, but it is not necessary. All fully know the tendency of it, viz.: to degenerate and weaken our race, physically, morally, intellectually, and socially, and in view of the inevitable result, is it not the duty of our legislators to do something to stop the downward course of our people? I think it is, especially as we have tried to show that it is worse to injure the health of an unborn infant than to inflict a sudden but curable injury upon an individual already born; and our courts would speedily and justly punish an act of that kind. Now I can see but one way out of the difficulty, and that is to enact laws restricting marriage in our land to the physically and mentally sound, by creating an examining board in a convenient central locality of each county or city, whose function it should be to examine, at stated times, all applicants for marriage license, etc., granting them a certificate if found sound; if not, to withhold it, and make it a misdemeanor for any one to issue the document without first seeing the certificate of health.

The law in order to be a success should be a general one, or couples would go from State to State and very little good could be derived from it; or each State could pass laws making it illegal for any persons to live in that State in relation of husband and wife without being able to satisfy the requirements of the law of that State. If some such plan as this would be adopted, I think there would be no doubt that the general health of our nation would greatly improve. It would be one of the greatest prophylactic measures a government could take to preserve

the health of its people. Our government considers itself fully vested with the power to institute and enforce quarantine and other measures to prevent the spread of disease, why would it not be as constitutional to pass good and sound laws touching the state of affairs as referred to in this paper, which brings infinitely more suffering and trouble into the world than even yellow fever, cholera or smallpox epidemics have brought. Then, again, should the above plan be adopted, I am of the opinion that the rejected applicants would decrease in numbers just in the proportion to the rigidity with which the law was enforced; and that in a few generations there would not be very many who could not pass a physical examination that would allow them the privilege of marrying.

I hope that our Government may be amongst the first of the great nations to adopt a prophylactic plan of this kind. As it leads the world in all other respects, why should it not in this matter also? There are other matters which should be considered in marriage which indirectly bear upon the future health. Chief among them is the financial condition. I do not mean that the parties should be extremely wealthy, nor do I mean that they should be very much the reverse, but I do think that before persons engage in marriage, they should be engaged in a business which yielded a good living; for without the necessaries of life, the health of both parent and offspring would be likely to suffer much, and the matter should receive their weighty consideration. On the other hand, I do not think it wise for a person otherwise ready for marriage to put it off until they can enjoy the luxuries of an affluent position, as many bright prospects, and what might be happy unions, are blighted from this very cause. So to these I would say, marry as soon as your financial prospects will admit, and do not wait for wealth. The station or occupation of an individual it would also be well to consider. For instance, children reared in the room adjoining a bar-room, exposed to all the evil influences connected with it, even though sufficiently nourished and clad, would be likely to suffer from it, morally and physically. But this is a matter, in which so long as callings of that nature are countenanced by law, very little can be accomplished. Marriage is a necessity to preserve the health and purity of a nation, for without it, and strict laws governing it, bastard children would be plentiful and many of them the production of individuals the very embodiment of physical abortion and moral depravity. Crosses between races of different colors would also be more frequent than they are now.

The last matter which I will mention, is the selection of a mate, but will not dwell particularly upon that, so long as people give a due prominence to the consideration of the other matters mentioned in this paper. For I am told by some, who claim to know, that there is a certain subtle substance or condition known and described as "love," which most persons deem absolutely necessary to a union, and as it is a matter which physiologists and physicians seldom take up, more than once or twice, we purpose to have very little to say on the matter.

To recapitulate briefly the headings of my subject: first, age; second, health; third, financial prospects; fourth, station, occupation, etc.; fifth, marriage a necessity; sixth, the selection of a mate; and the last matter should be made more of a business matter and less of an infatuation than it is by the masses of our young, or in other words, pay strict attention to the first five headings of my subject, then if that other element, or factor can be supplied, it is right to go ahead.

Hospital Notes.

PHILADELPHIA HOSPITAL.

(Clinic by Dr. Stryker.)

GENTLEMEN: The case now before us is that of a young woman who is suffering from mastitis, otherwise known as mammary abscess or inflammation of the breast. Mastitis may come on at any time, but it is most common during lactation; usually in the first week after parturition. This case, however, developed in the second week. This condition may arise in the breast which become engorged; from exposure to cold, or from rude treatment by the child. Where the nipples are tender or fissured, suckling causes such pain that the mother refuses the child; allows the ducts to become overfilled, and consequently a mastitis is set up. In all such cases protect the breast from cold; keep the ducts empty and remove all cause for irritation. The condition may become more serious and involve the glandular tissue itself as it has done in this case. As a rule, this is very painful. If the woman is strong and plethoric, leeches applied near the armpit give relief. Anoint the parts with warm sweet oil or lard to soften the tissues, and coax the milk out by gentle pressure from the periphery towards the nipple. If there is much fever, use hot lead-water and laudanum, covered with oiled silk. If this will not answer, an abscess will result which calls for poultices. The poultice should be changed every three hours. When pus is formed, make a free incision *along the line of the ducts*, at the most dependent portion, and introduce a drainage-tube. This may be the end of it, but this is not always the case, for multiple abscesses may form and fill the breast with sinuses, and as a result the future usefulness of the breast will be destroyed. Such a condition exists in this woman. In this case syringe the sinuses with lime-water, or sulphate of zinc, gr. ij to ℥j of water; or equal parts of dilute alcohol and iodine. Her strength has been kept up by good nourishing diet and wine; and a tonic of iron and quinine.

ICTERUS NEONATORUM.

During the remainder of our course, I wish to diret your attention to some of the most common complaints of young children; and I would first have you note the intense yellow color of the whole body of this child, which now is six days old. It is a condition of icterus neonatorum, due to an improper elimination of the bile, from a cause as yet not thoroughly understood. In mild cases it calls for no

treatment. In a case so marked as this give a gentle laxative—a small dose of sweet oil, repeated until good yellow stools are obtained, when the condition gradually leaves.

OPHTHALMIA NEONATORUM.

We have, in this same child, a condition of purulent ophthalmia, in which the eyes are markedly inflamed, the lids swollen, and the whole eye covered with a yellowish pus. This condition may arise from leucorrhœal or gonorrhœal discharges which enter the child's eyes during birth, or from soap or irritants applied by the nurse in cleansing the child In this case the irritation began on the second day with puffing of the eyelids and injection of the membranes. The secretion was thin and watery at first, but soon became thick, glueing the lids together. Hasty treatment is important in these cases. Mild cases, due to cold, dirt, or soap, often require to be kept thoroughly cleansed with warm water. Severe cases, from specific causes, require thorough cleansing with warm water and an application of nitrate of silver, gr. v to ℥j of water. Make the application yourself to the inflamed lids with a soft brush, and afterwards apply a weak salt solution to neutralize the excess of nitrate of silver. Keep the eye cleansed with bichloride of mercury 1–4000, and have a cloth wet with it over the eyes, to keep down inflammation and exclude light. When they begin to improve, substitute zinc sulphate, gr. ½–j to ℥ of water; three drops applied ter die. Don't cleanse with a syringe; use a brush or cotton. As obstetricians, it is your duty to see that the eyes of the new born are thoroughly cleansed with pure warm water. Inflammation in the eyes of young children, if allowed to continue, commonly results in the loss of sight, or destruction of the whole eye.

HARE-LIP.

Here is another child, four weeks old, who has a complicated case of hare-lip. As you see, the lip has a single fissure on the left side, and in addition there is a cleft palate. This is a surgical case, and I only wish to impress this fact: never do a hare-lip operation until the child is three or four months old, and well and strong, unless absolutely necessary, for they never stand these operations well when so young. Do the hare-lip operation first, and when it is healed properly attend to the cleft palate.

DIARRHŒA.

We will next consider the cases of these five infants who are suffering with mild diarrhœa of a non-inflammatory type, in which the bowels are relaxed and nausea is present. These attacks come on suddenly without any premonitory symptoms as a rule; maybe a slight rise in temperature, with a furred tongue, presenting red spots. It is of short duration, and is due to some undigested food in the alimentary tracts. The stools before you, on the napkins, are greenish or yellow, with undigested particles of food in them. This condition may come at any season of the year, and is most common in artificially fed children. If allowed to run on, it leads to disastrous results and becomes inflammatory. Small doses of mistura olei (castor oil, sugar, mint, acacia, and water) frequently repeated will give the best results in the end. Remove such causes as heat, cold, or improper diet. Spiced syrup of rhubarb is also good. If the oil fails to check it, give a dose of chalk mixture for its astringent action. Pepsin with chalk, or ♏ss. of tincture nux vomica with brandy stimulates digestion. Use no anodyne or opiate in these cases.

STOMATITIS.

Stomatitis, a condition not uncommon in young children, consists of a white curd-like deposit, resembling milk curds or a furred tongue, on the mucous membrane of the mouth and gums. It is simple and is indicative of some gastric derangement—most common in artificially fed children; but in these two cases before you, the children have been suckled by their mothers, and the cause is due to some external fungous deposit. It is easily controlled. Wash the mouth frequently with cool water. Occasionally rub the inside of the mouth with a mixture of borax and glycerin on a soft cloth. It is well to give a small dose of magnesia as a gentle laxative. When this condition comes late in entero-colitis, it is a premonitory sign of death. Ulcerations may set in, ulcerative stomatitis, which calls for positive treatment. Cleanse the ulcerated surfaces and touch with a crystal of alum, wet with water. Wash the mouth frequently with borax and myrrh. Regulate diet. You do not want to do a great deal for children; give as little in the way of medicine as possible.

CONSTIPATION.

I wish to call your attention for a few moments to a common complaint of childhood—constipation. Children begin with this condition in early life; and if present at birth or a few days after it, would suggest malformation. If the bowels of the new born are not moved in twenty-four hours, instigate an investigation and you may find a thin, web-like membrane over the anus. If simply a membrane, split it. More extensive malformation calls for surgery. Artificially fed children, as they grow older are annoyed with sluggish action of the bowels. Best treatment is to regulate diet; for if you will cater to the child, you will have less trouble than when you begin medicines, which must be continued if once begun. Habit has a great influence, and they should be encouraged to go to stool at regular intervals each day. If you are called to do something, use barley-water or oatmeal water with the milk as a gentle laxative. Resort to enemata rather than medication. Where medicines must be used, give syrupus rhei with magnesia, or a dose of castor oil may be necessary to clean the whole bowel. If the child is weak and lacks tone, give tincture nux vomica, ♏ss.–j ter die. Do not get into the habit of ordering a purge to children, but recognize the cause and regulate accordingly.

FRACTURE OF LOWER JAW.

Dr. Steinbach presented the case of a young man who had sustained a compound fracture, in the median line of the body of the inferior maxillary bone, with marked deformity. He was unable to maintain the parts in apposition by splints, wiring the teeth, or the Gibson bandage. Holes were made through the

alveolar process on each side, and the parts were drawn together and held firmly in position by a silver wire. The teeth were also wired, and after thorough antisepsis, a Gibson bandage with splint was appl.ed.

MEDICO-CHIRURGICAL COLLEGE.

REMOVAL OF A SPINDLE-CELL SARCOMA OF THE LOWER JAW.

THE patient, a colored woman, had been operated upon a year before, for a cystoma in the same region in which this sarcoma subsequently developed. This sarcoma involved the right side of the lower jaw between the symphysis and the ramus.

The operation consisted essentially in first making a vertical incision through the lower lip, ligating the inferior coronary artery, then separating the structures along the side of the bone and ligating the facial artery. The bone now being exposed, a circular saw driven by the dental engine was brought into use, and a section of bone removed leaving however, the whole lower margin of the jaw remaining in order to prevent the great deformity which would otherwise have resulted. The tumor having penetrated deeper down, the dental burr was used to bore out the remaining unhealthy structure, after which the inferior dental artery was plugged, and the parts cleansed and dressed.—*Garretson.*

FOR BAD BREATH.

Garrettson's prescription for bad breath is the following :

℞.—Acidi carbolici . . . . . gtt. xii;
Tinct. iodi comp. . . . . gtt. lxxx.
Glycerini . . . . . f℥ij.—M
Sig.—Put a pint of water and gargle five or six times daily.

TENOTOMY.

Goodman believes that the secret of the prevention of abscesses in wounds made in the operation of tenotomy, is to squeeze out all the blood contained in them, before applying a bandage.

FOR HIP-JOINT DISEASE.

Pancoast did some extensive muscle cutting in order to give relief to a patient in an advanced stage of hip-joint disease, dividing the tensor vaginæ femoris, sartorius, rectus, the gracilis, the adductor longus, and part of adductor brevis.

DIAGNOSIS OF HIP-JOINT DISEASE.

Hip-joint disease may be recognized, when, upon the patient's lying down, a flexed condition of the limb is observed, which upon being extended, raises the middle of the back. Upon the administration of ether, if the leg assumes a straight condition, the muscle should not be cut.—*Pancoast.*

VALUE OF SULPHUR.

Shoemaker thinks that sulphur is much neglected, considering its marked impression upon the liver and upon the sebaceous glands of the skin. The sulphide of arsenic, and the sulphide of calcium, have been used very effectively in various troublesome affections of the skin, both externally in the form of an ointment and internally.

ENUCLEATION.

Whenever an eye is in such a condition of disease as to render a restoration of sight hopeless and impossible, it is best to take it out, and thus prevent any sympathetic irritation or ophthalmia being set up in the other eye.

In the operation of enucleation, Keyser, first with scissors and forceps, cuts the conjunctiva in a circular manner of a sufficient diameter to allow the exit of the eyeball; he then, with the aid of a hook to bring the muscles into view, severs them from their attachments to the sclerotic, at the same time breaking up all inflammatory adhesions which may exist. Then, with a blunt-pointed curved scissors, glides down over the internal surface of the eyeball, and with one clip divides the optic nerve.

The pain experienced by the patient from the cutting of the nerve is so intense, that Keyser generally gives a little ether just before this stage of the operation. The pain in these cases, however, is not due to the division of the optic nerve, but to the cutting of the ciliary nerves which run along with the optic and are distributed to the ciliary body.

CICATRIX OF CORNEA.

This cannot be removed in the ordinary manner—the scalpel is interdicted. The *modus operandi* is: tattooing with the very best India ink, having previously used cocaine to render the operation painless. Tattoo slowly and carefully, as considerable inflammation is likely to result. If the latter should become too marked, allay it by using applications of cold water.—*Keyser.*

WILD HAIRS.

Destroy the hair-bulb by electricity. This is done in the following manner: Pass a tiny needle down along the shaft of the hair into the bulb, and apply the galvanic current, as strong as required. Small bubbles will immediately appear at the entrance of the needle. These show that the electrictity is acting. —*Keyser.*

PERIBOMIAN TUMORS IN CHILDREN.

Dr. Keyser recently removed three of these tumors from the eye of a child two and one-half years of age. The doctor says they rarely occur thus early, the usual sufferers being individuals from twelve to fifteen years of age. He had never before seen one in a child so young.

DISCISSION OF CATARACT.

Congenital cataract should receive immediate attention. Delays are not only useless but dangerous. Discission ought to be performed soon after birth, as early as the seventh or tenth day. To the initiated this is a simple operation, for it requires but three instruments, a speculum to separate the lids, forceps to hold the ball, and a needle, called Bowman's needle, to make the puncture.—*Keyser.*

CARE OF THE NEW-BORN.

Never trust the nurse to wash the new-born infant's face. Doctor, this is *your* business. See to it that you thoroughly cleanse mouth, nose, ears, and eyes, especially the latter. Not so to do is a sin

of both omission and commission. Remove from the eyes every trace of vaginal secretion, for these left to remain are so much bad seed sown in good ground—bound to root and grow, not after many years or many weeks, but after a few days.—*Keyser.*

CHANCROIDS.

For these, there is nothing better than simple iodoform.—*Stubbs.*

ORTHOPEDIC HOSPITAL.

A SINGULAR CURE FOR EPILEPSY.

DR. MORTON some time since operated for equino-varus upon a boy subject to epileptic fits. These fits were congenital and of very frequent occurrence. Indeed, upon the morning of the day of operation the patient suffered from no less than five attacks, yet, strange enough, after the tenotomy the epileptic fits suddenly ceased; nor have they since occurred.

RESECTION OF BONE.

Morton, in a bad case of varus, where the back of the foot had become callous by being walked upon, removed a wedge of bone from the tarsus, dissected out the indurated skin, performed the necessary tenotomies, and secured a perfect result.

DEFORMITY OF THE WRIST.

For a slight deformity of the left wrist resulting from a sprain, Dr. Goodman recommended massage.

SYNOVITIS.

It sometimes happens that chronic forms of this trouble do not readily yield to the treatment by tapping. When this occurs it is well to inject a little bichloride. This induces more active inflammation. It is well, however, to use with the bichloride some muriate of ammonia, to prevent its coagulating the albumen in the tissues.—*Goodman.*

TO DETECT FLUID IN A JOINT.

For anyone who is likely to have difficulty in determining the presence of fluid in synovitis, it would be well to remember that a *positive* indication of its existence would be the rebounding of the patella when tapped with the finger. Another indication, not nearly so positive, however, is fluctuation of the patella.—*Goodman.*

PENNSYLVANIA HOSPITAL.

HEART TROUBLE.

MUCH of the regulation treatment for valvular heart trouble Longstreth thinks is misdirected. Says he: "Orthopnœa is relieved by a brisk purgative of calomel, when it will not yield to the regulation treatment with digitalis and cupping. The trouble lies behind, not in front, of the heart. Once the valves are affected we cannot restore them to their normal state; treatment should, therefore, be directed to the point where it would be most beneficial, namely, the liver. Death is more frequently caused by non-nutrition, due to a failure of the liver to act properly, than by a failure of the heart due to defective valves. George Shaw, of beer-parade notoriety in this city, served as a clinical subject for five years. He had most marked valvular trouble, and suffered exceedingly from orthopnœa. Of the latter he was always relieved by a brisk purgative. He finally died, not from his heart trouble, but from red atrophy of the liver."

IMPACTED FRACTURE.

In an impacted fracture of the neck of the thigh bone do not disturb the impaction.—*Ashhurst.*

A MEDICAL MAXIM.

One of the earliest maxims I ever learned was from dear old Dr. Carson. It was his custom to say that when a patient complained of trouble in the chest we should look for the cause below the diaphragm, and when he complained of trouble in the abdomen we should look for the cause above the diaphragm.—*Longstreth.*

CIRRHOTIC LIVER.

At an autopsy by Longstreth a cirrhotic liver was shown to have indirectly caused the death of a patient suffering from a slight attack of pneumonia. By its contraction the liver was unable to relieve the heart of its overflow, consequently the blood was dammed up there, coagulation set in, and death was directly caused by heart-clot. Examination showed the ventricles clogged with blood clots.

AFTER-TREATMENT OF ABDOMINAL SECTION.

Hunt does not believe the rationale of the after-treatment of abdominal sections now in vogue to be in accordance with the established principles of therapeutical surgery. Says he: "I cannot see why the great principle of rest is not applicable in wounds of the intestines, as well as in wounds or fractures of the extremities. Why not place a wounded intestine in splints as well as a fractured extremity? Would not union of an incised gut be more likely to occur with the bowels quiet, in a state of rest, than in a state of peristaltic action? Then why not administer opium?" He referred to himself as having recovered from typhoid fever after perforation, by having had his bowels kept in a state of rest by the administration of opium, and added that many of the profession disbelieved his having had perforation, because he didn't die to prove it.

DIPHTHERIA.

Disinfect and keep nasal passages clear with solution of borax, ten grains to the ounce, with a little glycerin added if much dryness exist. Swab or spray the throat with a solution of the perchloride of iron, adding syrup or glycerin if much dryness exist.—*Longstreth.*

POLYCLINIC.

A PATIENT treated by Mays, two years ago, for chronic bronchial pneumonia, in whose left lung percussion dulness was elicited throughout its entire extent, and in the apex of which consolidation had set in, returned in a comparative good state of health, having given birth to a child and buried her husband in the meanwhile. Her treatment consisted of the regular tonics, rest in bed, and the application of a linseed poultice on the chest, continued for several months.

TOBACCO-HEART.

SHIELS (*Pacific Medical Journal*) gives the results of a little collective investigation of his own. He propounded a series of questions to the members of the New York Academy of Medicine, and the answers are analyzed. The first question was, "What constitutes tobacco heart?" All who answered excluded organic lesions, regarding it as a functional derangement, characterized by irregularity, irritability, palpitation, and intermission. Some also mentioned uneasiness and pain.

Does it produce marked irregularity of the pulse? Some said it produces intermissions; one believing tobacco to be the most common cause of this symptom. Some say it increases the frequency of the pulse; others that it lessens it. Probably in some cases it stimulates, in others depresses.

Does it cause hypertrophy or valve-disease? Some affirmed that it does cause hypertrophy; and the author is himself of this opinion. Most anwers were in the negative.

The majority also answered that tobacco heart is not a common affection. Considering the number of tobacco users the condition must be rare; among moderate smokers it never exists, and it is the first sign that excess has begun.

People of a nervous type are more apt to suffer from it than those who are phlegmatic.

Cigarettes were held to be most injurious; and Dr. Shiels agrees with this; giving as a reason that they are used by younger boys, and are apt to be used almost continuously, and the smoke inhaled. The least injurious method is the Turkish pipe. The effects are, however, chiefly dependent on the quantity of tobacco used.

Few could give an estimate of the proportion of smokers affected, but the author puts it below five per cent.

On the question of the effect on mental activity, the answers were contradictory; about an equal number believing that it increases, lessens, or does not affect the brain activity. Some referred to its power of steadying and soothing. Dr. Shiels believes they are all right; each correctly describing the effects in the cases observed by him.

Many found it caused insomnia. As to a permanent effect on the brain the answers were generally negative. One, a superintendent of an insane asylum, reported five of his cases were due to tobacco. The author doubts this; as well as the St. Thomas' Hospital reports of three cases of tobacco delirium.

There was no consensus of opinion as to the effect on the spinal cord; but of ninety-one answers nearly all affirmed that it caused tremulousness of the hands.

The tendency was to the effect that as regards the teeth, tobacco is preservative. Evidently it cannot then be a cause of dyspepsia.

Pharyngitis is a very common condition in smokers. The answers as to digestion tended to show that tobacco is an aid, unless used to excess, or just before meals. Many stated that tobacco acted as a laxative.

Among the young it causes emaciation; also when used to excess or by chewing. Some denied this, and one affirmed that eighty per cent. of smokers are corpulent.

Many said that no effect upon the lungs was produced, but many were of the opinion that when the smoke was inhaled it caused irritation of the mucous membrane. Dr. Shiels speaks of a peculiar sharp, short cough, in cigarette smokers.

As to tobacco blindness, two oculists out of seven had seen cases in which alcohol was not used. The answers by general practitioners were negative. Amblyopia is an exceedingly rare result of tobacco smoking, even when practised to excess.

The use of tobacco by the young is harmful in the extreme, and should not be allowed previous to the age of seventeen years, or even twenty-one.

Does tobacco ever shorten life? Nearly all answer that they have never seen it cause death directly; while many note it as a coöperating cause.

Is the moderate use of tobacco hurtful or beneficial? Most say neither; but Dr. Shiels thinks that the general use of the weed indicates some beneficial action. In spite of laws and crusades against it, the use of tobacco has spread to nearly every part of the globe. This fact goes to show that it must fulfil some human want. Excluding youth, idiosyncrasy and excess, its moderate use afterwards has a beneficial effect.

We have given a comprehensive sketch of this paper, which we look upon as of considerable importance. Its freedom from bias is especially commendable; as, in general, writers upon tobacco have been evidently prejudiced, and its opponents in particular have shown themselves fit to be classified with the anti-vaccinationists.

Our own observations, however, are not quite so favorable to tobacco. We have examined the hearts of a great many young men, and found the irregularity mentioned by Dr. Shiels in a greater proportion

of cases than he admits. Fully ten per cent., perhaps fifteen, of smokers suffered from it. On one occasion we examined a large class of students, and recognized a number as excessive smokers by this irregularity of the heart. The argument deduced from the universal employment of tobacco is of doubtful authenticity. It could quite as well be used to justify the use of alcohol; perhaps of many immoralities which are very generally practised.

Idiosyncrasies in regard to tobacco are comparatively rare. We have met with one case in which an inability to form a tobacco habit was transmitted to the third generation. In this family there was also a notable tendency to nausea upon riding in stage coaches, railway trains, or even in the street cars; similar to sea-sickness.

THE BISHOP CASE.

THE physicians who performed the autopsy upon the body of the mind-reader, Bishop, are probably satisfied that they made a mistake. No possible good to science can excuse the haste with which they proceeded to operate, without the previous permission of either the family or the Coroner. Even dead men have rights, which are protected by law, and the consequence of their imprudence may fall heavily upon Dr. Irwin and his associates.

Besides, they are confronted with the ghastly possibility that the mind-reader was not dead. He is said to have been subject to catalepsy, and to have twice lain in trance so profound that he was thought to be dead; this lasting over two days. This, the newspaper account, obtained from the excited female relatives, will, of course, be heavily discounted by the scientific reader. We think the probability of Bishop's being alive at the time of the autopsy is slight. Still the question has been raised; and in justice to the physicians, as well as out of regard to the feelings of the relatives, the most searching investigation must be held and the matter settled definitely, to the satisfaction of all concerned.

The condition known as trance is not often met with; and among recorded cases the death-trance is exceedingly rare, though the novelists have rendered it familiar. Still, as Gowers says, the most ghastly incidents of fiction have been paralleled by well-authenticated facts. He enumerates as the signs of life in such cases the absence of decomposition, the normal appearance of the fundus oculi as seen with the ophthalmoscope, and the persistence of muscular electro-excitability. In a case observed by Rosenthal, the muscles still responded to electric stimulation thirty hours after the supposed death; and in forty-four hours the patient awoke.

Ferrier gives as the first sign of death: cessation of the heart's action. Rayer states that the heart cannot stop for more than seven seconds without death; but Ferrier thinks a longer time should be allowed. The use of the stethoscope is evidently regarded by him as a sufficient means of establishing this fact. If the cessation of the heart's action be established, no other sign is necessary. As accessory signs, he speaks of cessation of respiration; as ascertained by holding a mirror or a flock of cotton-wool to the mouth, or by placing a cup of water on the chest and observing whether the reflection on its surface remains still. Rosenthal says that the existence of electrical contractility indicates life, or that death has occurred within three hours. After death the body cools at an average rate of 1° F. hourly. Hypostasis occurs usually in from eight to ten hours after death; rigor mortis may appear immediately or at any time up to twenty-four hours; while putrefaction is evident on the third day.

Until the facts of this case have been made public by Drs. Irwin, Ferguson, and Hance, we may surely assume that they made us of all the resources of their art to satisfy themselves that Bishop was really dead; and if this be the case, the chances of their having been mistaken are too slight for serious consideration. One apprehension on the part of his friends may be at once set at rest; there is not the least possibility of consciousness having remained in so profound a trance, were this really an instance of that state. It is only in the slighter forms of trance that the patient remains conscious, forms which resemble sleep, but not death.

Annotations.

INTRA-PULMONARY INJECTIONS.

IN the Boston *Medical and Surgical Journal*, Bowditch details two cases of phthisis treated by intra-pulmonary injections. The first case is that of a man whose diagnosis of phthisis is, to say the least, doubtful. The symptoms as given indicate rather a fetid bronchitis, with the formation of bronchiectases, in which the secretions became decomposed; giving his breath a gangrenous odor, and leading to a septicæmic condition. No statement of the temperature range is given, but an examination of the sputa revealed no bacilli. Three intra-pulmonary injections of "carbolized iodine" were made, at intervals of seven and ten days; and the patient recovered so far as to permit of his leaving the hospital and assuming the duties of a hotel employè. Six months later he was seized with symptoms of undoubted tubercular phthisis, the bacilli being found in the sputa; and the intra-pulmonary injections were not followed by even a temporary improvement.

There is no evidence in the history before us that there was any tuberculous element in the first attack; which, occurring in a person predisposed to phthisis, simply prepared a suitable field for the culture of the tubercle bacilli, of which they took advantage, when dissipation had reduced the patient's strength somewhat.

The second case was as follows:

J. J. C., man, twenty-six, single, clerk in Boston. Father died of phthisis at seventy-two. Mother of "liver complaint." Habits good. No venereal, ma-

larial, or rheumatic history. Never ill until three months ago, at which time he took cold when down the harbor, and since then has had constant and distressing cough with muco-purulent expectoration, occasionally bloody. Rapid loss of flesh, and night sweats. Hemorrhage two weeks before entrance. No appetite. No sleep, owing to cough. Bowels regular. Micturition normal. Pulse 110; temperature 101° (P.M.). Examination showed marked emaciation, and general characteristics of advanced phthisis. Percussion revealed decided dulness in the upper right chest down to third rib; less marked, but noticeable, below this level. Down to third rib respiration was bronchial and amphoric, with numerous coarse bubbling râles; below, with a sharp line of demarcation between the two regions, coarse moist râles throughout right front were heard.

Dulness in upper half of right back with moist râles throughout. In the upper portion breathing was rather obscure. Questionable râles heard in left back between spine and angle of scapula. No other special abnormalities could be found. Patient was ordered extra diet, a cough syrup, the compound syrup of hypophosphites and whisky, ℥ss t. i. d.

The only examination for bacilli recorded gave a negative result. The injections caused some improvement in the local symptoms, but the patient failed steadily and died three and one-half weeks after his admission to the hospital. Now, we submit that this was not a tuberculous case. The points against the tubercular theory are: the inception; coming from a cold, contracted while out on the bay: where no good Bostonian would admit the existence of bacteria. The hemorrhages, the low temperature, the dulness and the absence of bacilli, with the rapid wasting and speedy death, all point to a simple inflammatory disease rather than a tuberculous one. The bacillus is not the only cause of pulmonary inflammations, and the clinical diversity between bacillar and simple inflammations is distinctly defined.

The good effect of these injections in these cases, is, however, of much interest, and we venture to hope that this method of treatment may in the future prove of great value; if we can rid ourselves of the idea that it is a germicidal application, and utilize the agent as we would in the treatment of an ulcer in a more accessible locality.

THE TIMBY SYSTEM.

THE most distinctive feature of our modern social life is the Trust; by which we mean the combination of persons actuated by a common impulse, to secure their objects the more readily. We have railway trusts, whose object is to squeeze the greatest possible amount from the people for supplying them with transportation. The great flats which form so conspicuous a feature in New York, are combinations by which a number of families secure the comforts of modern house-keeping at a less cost than they could obtain the same for in separate residences. In consonance with the prevailing tendencies comes the Timby system, which aims at supplying pure air, heated in winter, or cooled in summer, distributed from a central depot of supply to the contiguous district. The company provides a plant suitable for supplying a community of 50,000 persons. From the central depot mains are laid along the streets, below the frost line. In these conduits run hot-water pipes, which heat the air; the latter being drawn from the top of a high chimney and propelled by a fan. The hot-water pipes do not enter the houses, but stop at the street; smaller pipes being employed to conduct the heated air through the buildings. In hot weather the air thus forced through the houses is first cooled, by the use of ice or of freezing mixtures. This is a provision of the utmost importance, as the difference of a few degrees often means life or death to invalids, especially children. The cost of heating is reduced to a minimum, as the cheapest grades of fuel can be utilized; such as that which forms the great culm banks in the coal regions. This has been used at the Murdock Free Hospital, in Boston, and is said to be the cheapest fuel obtainable.

The air thus introduced can be impregnated with disinfectants if desired; and these can be limited to a single house or room. The danger from fire is greatly lessened, the annoyance from the use of coal, the dust, dirt, ashes, making up and attending to fires, etc., are all done away with by this system. Explosions cannot occur, as the water pipes do not enter the houses, and the pressure in them is limited to five pounds to the square inch. Electric wires can be laid in the same conduits, and the power connected with the plant may also be used to run the dynamos.

The inventor of this system is Theodore R. Timby, who also invented the revolving turret of the monitors. The President of the company is Dr. William A. Hammond.

Health, economy and comfort will be subserved by the adoption of this method, and we hope to chronicle its successful introduction.

THE Canada *Lancet* argues that a six-month's session for the Medical College is long enough, and we heartily agree with our contemporary. There is a limit to all things human; and despite the advances of the age, the human mind has a limit to its receptivity. A season of activity must be followed by one of repose, as the night follows the day. The muscles of the prize fighter cannot be kept in condition very long, or the state known as "over-trained," supervenes. Even the base ball or cricket player becomes stale after a prolonged season, and his cunning fails him; the ball eludes his weakened grasp. After six months imbibition of knowledge from a dozen different sources, the medical student reaches a pitiable state of super-saturation; and it is more than likely that further effort would result in his forgetting what he had already learned. Better add another year to the course and grade the studies, and and keep the term at six months.

THE death of Minister Rice from œdema of the glottis recalls the fact that Washington died of the same affection. These cases are not very common.

Paris Letter.

ANTIPYRIN IN DIABETES.

PROF. PANAS has communicated to the Academy of Medicine two cases of diabetes, complicated with cataract, in which he employed antipyrin with success; and from these cases and others of Dr. Germain Sée's and Dr. Robin's, it is clear that this drug has an antiglycogenitic action at once efficacious and prompt, and that it will succeed where other drugs fail. It is effective even when a certain amount of feculents are allowed as food. The dose should be three grammes per day. The drug should not be continued constantly. It should be given for a week or ten days and then a period of repose should follow, while the usual regimen should be instituted. This diet, which is so fatiguing to these patients, is one of the reasons for giving antipyrin, as it allows the patient to take ordinary food during the time he is taking the drug, and thus gives him a rest from the regimen. In short, an alternation of the usual regimen with antipyrin is now the accepted best treatment for diabetes. M. Dujardin Beaumetz claims that he first indicated this treatment, and M. Worms says that it is possible that all the antithermic drugs act in the same way. He used sulphate of quinine ten years ago in diabetes, and still thinks well of its action, which is much the same as that claimed for antipyrin in such cases, and as its innocuousness is well known, it is a pity that it is not more often used in all forms of diabetes, particularly the nervous form, the most frequent of all.

What is the duty of a physician when he sees death certain?

This question has been lately treated by Dr. Goix. First of all, is it necessary to speak at all? This must be answered in the affirmative. Certainly a doctor should speak as soon as he sees death imminent, and this for many reasons. The family may wish to call other members to see the patient, and, above all, it may be that wills and other last testaments should be prepared. Why is a doctor called into a house? To treat a person who is ill no doubt, but he is also expected to keep the family informed of the probable termination of the illness. After the treatment what interests them most is to know the prognosis, and it must be considered wrong for a doctor to undertake to treat a patient without looking upon the question of whether he is likely to get well or not. Frequently complaints are made of a doctor, not that he did not cure the patient, but that he did not let the family know that it was a serious matter, and that there was danger to life. The strict duty of a physician is to notify the family as soon as he knows that there is danger.

The next question that arises is, to whom shall he speak? To the patient or to the family? As a rule, one should never tell a dying man that his case is serious, and that he will not recover. This, however, is no reason for saying to him that he will get well, nor does it prevent speaking to some member of the family, or if this is not possible for any reason, then it becomes the duty of a Christian doctor to notify a clergyman of the patient's denomination of the facts, and allow him to act.

The last point is, when must a physician speak? The moment there is certain peril or probable danger, and it is important not to act too late, so that the patient will still have active knowledge of his state, and can act legally if needed. On the other hand, it is never too late to speak, and if one is called in late, and the patient is really dying, it is well to insist on a clergyman's being called, because people often wait until such ministrations are no longer of use. It is therefore, a physician's duty to prevent this by giving prompt notice. Even in cases of lunatics, it is well to give prompt notice of their approaching death, as they sometimes have lucid moments at this time, that may be taken advantage of by a clergyman to offer the last consolations of religion. Certain diseases, such as angina pectoris, aortic insufficiency, labio-glosso-laryngo-paralysis, etc., are causes of sudden death, and it is here the duty of a doctor to say "that at this moment he is not alarmed since the patient might live for a long time," but he should, nevertheless, tell the relatives that the patient might die suddenly, and let them take such precautions as they like under the circumstances.

Quinine Wines.—These very useful tonic wines are rarely good, most of the usual brands contain a very feeble quantity of the active principle, so that it is much better to give a formula to patients needing such drugs. No matter how honest the druggist is who prepares "quinine wines" or cinchona wines, they are seldom efficacious. Dr. Huchard gives the following, which he uses with success in small wine-glass doses:

℞.—Grenache wine . . . . . 400 grammes.
(Any good strong white wine will do)
Bitter orange-peel syrup . . . . . 50 grammes.
Soft extract of cinchona,
Glycerin . . . . . āā 25 grammes.
Tincture of coca . . . . . 15 grammes.—M.

Sig.—Rub the extract of cinchona up in the glycerin (to prevent the wine's clouding by precipitation of the cinchona resins), and then filter several times when mixed. When there is constipation the coca tincture can be replaced by 15 grammes of rhubarb tincture.

Discovery of an Artificial Vaccine Matter.—Dr. Woytkoff, of Moscow, Russia, while working on the study of the active principle of genuine vaccine matter prepared an artificial lymph which seems to possess all the properties of vaccine matter. Its inoculation produces pustules in the same way, and they confer immunity quite as well as the real matter. The preparation of this lymph and its culture has its origin in the theory that certain pathological processes are provoked by the association of several kinds of microbes, and not of one alone. M. Woytkoff presented to the Medical Society of Moscow a calf bearing the characteristic pustules which he produced by his artificial lymph. The theoretical and practical results of this discovery are of great importance. We merely mention it at present and await further experimentation to confirm the facts.

Treatment of Diphtheria.—Dr. Jules Simon, of the Children's Hospital, gives the following formula:

Local Treatment.—To be used with hydrated cotton wrapped on a pair of pincers.

℞.—Salicylic acid, 0.50 centigrammes to 1 gramme.
Alcohol . . . . . q. s. to dissolve.
Glycerin . . . . . 40 grammes.
Eucalyptus (infusion) . . . . 60 grammes.—M.

Sig.—Apply every hour in the day and three times during the night.

If the false membranes are thick and adherent, also use the following, in the same way, two to four times a day in the intervals:

℞.—Perchloride of iron,
Glycerin . . . . . āā 10 grammes.

Besides this, irrigation of the throat is performed every two hours with aqua calcis, Vichy water, or carbolized water, one to a hundred; but this last is not so much liked as medicinal lime-water.

If there is swelling of the glands of the neck, apply the following pomade on a wadded bandage around the neck:

℞.—Ext. belladonnæ . . . . . 2 grammes.
Potass. iodid. . . . . 1 gramme.
Lard . . . . . 30 grammes.—M.

Internal Treatment.—Alcohol in all its forms, wines and liquors, champagne, etc. The youngest child can take large doses of brandy, thirty to forty grammes a day is not too much for a three years old. To each dose of grog add a drop of perchloride of iron, giving ten to twenty drops in all per day of this.

When the child is over six years of age give also:

℞.—Cubebæ . . . . . 60 grammes.
Copaibæ . . . . . 30 grammes.
Ferri subcarbonat. . . . . 4 grammes.
Bismuth. subnitrat., q. s. to form the preparation into a solid mass, and divide it into "boluses" the size of the point of the little finger, and give four of these per day.

Treatment of Typhlitis.—Prof. Bouchard gives the following indications: 1. To calm the pain. 2. To place the intestines in a state of repose and reduce the digestive ferment to a minimum. 3. To produce asepsia of the large intestine.

For the first, use cataplasms, mercurial ointment with belladonna, and morphine injections. Secondly, as to the alimentation: milk with alkaline water added to it, or the yellow of eggs; all solids to be avoided and all fermentable substances. The bowels are to be kept free by laxatives, such as sweetened water and a spoonful of magnesia, or a dessertspoonful of castor oil. No violent purgatives must be given. Third, for intestinal asepsia: twice a day make a rectal injection with a quart of the following solution, which must be first heated to 38° centigrade:

℞.—Borate of soda,
Tincture of benzoin,
Camphorated alcohol . . āā 5 grammes.
Water . . . . . 1000 grammes.—M.

The following formula is given for *exalgine*, spoken of in our last letter:

℞.—Exalgine . . . . . 4 grammes.
Kirsch . . . . . 40 grammes.
Dissolve and add
Distilled water . . . . . 80 grammes.
Syrup (simp.) . . . . . 30 grammes.—M.

Sig.—Each tablespoonful contains 0.25 of exalgine, and take from one to three in twenty-four hours.

International Medical Language.—One of our local medical societies lately undertook to study up this question, and after a long debate in which all the various tongues were tried, both dead and living, and combinations of both, including what is now called *volupük*, a vote was taken as follows:

1. Is it advisable to adopt an international scientific language? Unaminous vote. Yes.

2. Ought it to be a dead language? No.

3. Shall it be the French language? Majority vote. Yes.

This beats the fixed laws of the Medes and Persians, and *is quite French.* Victor Hugo used to say Paris was the centre of the world, and French was the language of the world, but we fancy we hear some one say, "What egotism!"

Idiosyncrasy for Quinine.—It sometimes happens that persons suffering from intermittent fevers cannot take quinine without its causing erythema, accompanied by severe itching; but if a solution of bromide of sodium, 1 in 40, be used, giving a dessertspoonful of it every two hours, quinine may be given with impunity.

Hypodermic Injections of Morphine.—Dr. Huchard gives a practical point about these everyday operations that has considerable value. It is to insist on complete silence and repose, not only on the part of the patient, but on all around.

It is well known that sometimes an injection has no effect, and Claude Bernard showed that morphine does not suppress sensibility as chloroform does, but that it provokes a sort of exaggeration of excitability and a considerable sensibility to noise, and it is certain that a morphine injection will completely lose its effects if the precaution is not taken to make all keep quiet about the patient; even the curtains should be drawn to have a certain amount of obscurity—if it is given in the day time.

Itch.—Dr. Paul proposes the following soap:

℞.—Marseilles soap . . . . . 100 grammes.
Petroleum,
Alcohol . . . . . āā 50 grammes.
Wax . . . . . 40 grammes.—M.

Sig.—Soap the parts three or four times a day.

THOMAS LINN, M.D.

PARIS, April 26, 1880.

Letters to the Editor.

IN your issue of May 11, 1889, in giving the discussion on typhoid fever in your reports of the Indiana State Medical Society of this year, you make it appear that I recommended the giving of oft-repeated doses of calomel in two-grain doses, which is very different from what I did, or would recommend.

I give one-tenth of a grain, every four hours during the day, leaving it off at night. Will you please make the correction, as I think two-grain doses, often repeated, would be very hazardous, and would be far from producing the results I would desire from it.

Very respectfully,

W. O'NEALL MENDENHALL, M.D.

RICHMOND, INDIANA, May 13, 1889.

ABNORMAL CONDITIONS IN LABOR.

LABOR cannot be regarded as a disease, but is a physiological phenomenon taking place about nine months from the last menstrual appearance, in which certain peristaltic contractions and relaxations of the muscular walls of the uterus take place, resulting in the expulsion of the uterine contents without artificial aid, providing no perversions, or abnormal pathological conditions manifest themselves throughout its course; yet, no cases come under the practitioner's notice, the welfare of which depend more upon the honesty, proficiency, skill, and good judgment of the physician than those of labor. A true physician, one who has the interest of his patients at heart, will thoroughly acquaint himself with the mechanism of labor, so that he may intelligently note its progress. A slight neglect of duty, improper or injudicious meddling on his part may produce intense and prolonged suffering, or even cause the death of the patient.

The old axiom, "Let nature alone and it will accomplish its work," holds good in the majority of cases; yet how often do we find a patient suffering intense agony for hours, the doctor at her bedside, trying to console her by telling her that God and nature intend her to suffer thus for her offspring, that it is her duty to bear with patience the affliction thus brought upon her, that all will be right in due time; when, perhaps, at the same time some abnormal condition is present retarding the progress of labor, which might, perhaps, be rectified by simple and harmless means, and thus relieve the patient of her prolonged and uncalled for sufferings, were it not for the negligence, indolence, or, perhaps, ignorance of the physician. It is the accoucheur's duty carefully to watch every symptom as it manifests itself in the case intrusted to his hands, and, as far as possible, correct every abnormal condition that may arise during the progress of labor. He should ever be ready to assist nature in the accomplishment of her object as much as prudence and good judgment will allow.

Among the abnormal conditions of the uterus that may occur during the first stage of labor, are the following: inefficient action of the uterus, in which the contractions may be feeble or irregular; a condition that will torture the patient for hours without any progress. In order to rectify this, we must seek for the cause; perhaps, among the following: a torpid state of both mind and body, a deranged condition of the digestive organs, irritation of the os and cervix uteri, uterine inflammation, rheumatism of the uterus, plethoric condition of the uterus, excess of liquor amnii. Again, there may be rigidity of the os uteri, obliquity of the uterus, rigidity of the vagina. The anterior lip of the os uteri may be retained between the head of the child and the symphysis pubis. Or there may be causes referable to the child, such as rigidity or toughness of the membranes, etc.

Then there are abdominal conditions that will retard labor in the second stage, which we will not mention now; nor need we give treatment, as the text-books are too convenient of access to the physician to render it necessary. Suffice it to say that were we more diligent in watching our cases we should have less use for the forceps or the perforator and the crotchet. There would be less laceration of the perineum, and more hearty and robust mothers.

D. M. BLOOM, M.D.

NEW WATERFORD, O.

The Inquirer.

SIR: I am anxious to obtain medical practice in Philadelphia, either as assistant, or partner, or as successor to a gentleman wishing to retire. I am not particular as to class of work, provided prospects are fairly good. I hold the diplomas of the Royal College of Surgeons, London, and of the Dublin College of Physicians, and am an Associate in Arts of Oxford University. I am thoroughly experienced in all branches of general practice, but particularly in gynecology and diseases of children, of which I have made a special study. Acquainted with French and German. Address, H. G., office of this journal.

HALL'S CATARRH CURE.

Take of iodide of potassium	60 grains.
Comp. tinct. cardamom	4 fluidounces.
Comp. tinct. gentian	12 "
Caramel to color.	

—Druggists' Circular.

HAIR TONIC.

To prevent the falling out of the hair, Dr. Bordet (*Med. Chirurg. Rundschau*) gives the following formula:

Take of carbolic acid	30 minims.
Tincture of nux vomica	2 drachms.
Comp. tinct. of cinchona	1 fluidounce.
Tinct. of cantharides	30 minims.
Cologne-water	1 fluidounce.
Cocoanut oil, to make	4 fluidounces.

Mix.—To be applied to the scalp twice a day with a small sponge.

—Meyer's Druggist.

FOR MOTHS.

Use with an atomizer:

Alcohol	500 parts.
Naphthalin	10 "
Carbolic acid	10 "
Camphor	5 "
Spirit of lemon	5 "
Oils of thyme, lavender and savine (of each)	2 parts.

—Meyer's Druggist.

ANTISEPSIS IN LABOR.—(*L'Union Med.*), 1888, Dr. Louis Roulin claims that inter uterine, and even vaginal injections, are accompanied with danger, and recommends in normal labor the following methods: First wash the hands with a 1 per cent. solution of chloral, then before the child is born wash the sexual organs and neighboring parts with the same solution.

After the birth of the child repeat the washing; then apply to the vulva salolgauze, on this hydrophile, and over all cotton wrung out of a 1 per cent. solution of chloral. This dressing is to be renewed every six hours. He uses chloral because it is not poisonous and acts just sufficiently antiseptic.

Book Reviews.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS, Consisting of Original Treatises and of Complete Reproductions, in English, of Books and Monographs Selected from the Latest Literature of Foreign Countries, with all Illustrations, etc. New York: William Wood & Co., 56 and 58 Lafayette Place. Published monthly. Price, $10 a year; single copies, $1. May, 1889.

Sir Henry Thompson, the distinguished English surgeon, is the author of the first paper in the May number of the Monograph, On the Preventive Treatment of Calculous Disease and the Use of Solvent Remedies. This interesting topic is treated of by the writer in three lectures. The first is devoted to the early history of calculous disease and the treatment best adapted for its prevention, the second to the dietetic treatment of patients excreting uric acid in excess, and the third on the treatment of stone in the bladder by solvents; its history and practice. All the lectures just alluded to are most interesting, but the one which is most instructive refers to the dietetic treatment. The author insists upon the avoidance of alcohol, and says when you admit some compromise in the matter advise a sound light wine, the ordinary produce of the Moselle, if possible; in its absence, that of the Rhine or Bordeaux.

Sprains; their Consequences and Treatment, by Surgeon C. W. Mansell Moullin, of London, occupies the remaining portion of the volume. Among the other useful agents recommended may be named faradization and galvanization, Dr. Moullin adding that galvanism is more effectual than the interrupted current. The May issue of the Monographs is both interesting and practical, the papers that it contains being of essential value to physicians.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN By JAMES NEVIN HYDE, A.M., M.D. Philadelphia: Henry C. Lea's Son & Co. 1888.

The success of a book is usually to be judged in proportion to the demand for, and its appearance in, subsequent additions. Five years having elapsed since the appearance of the first edition of the work, it looks very much as if the book did not take. Dermatology has made most rapid advancement during the period just referred to, and if the author had been a little more practical and a little less theoretical in his writings, he would have produced in the volume before us one that, as he says, is for the use of students and practitioners. The additions in the present edition have too much bidding for the commercial advancement of the author. In other words, the original first edition, which, from the late appearance of the second, so signally failed, has been enlarged by adding such points as hold the author up to the esteem of himself and those who may glance through its pages. The first part of the work has very few good features, not any of which are original, and the rest is largely made up of a compilation from other well-known treatises upon diseases of the skin. The small portion of the book devoted to therapeutics is woefully deficient, many of the modern additions made to this department within the last five years not even being mentioned. The author has thus shot very wide of his expression upon his title page, "designed for practitioners and students."

THE MEDICAL ANNUAL AND PRACTITIONERS INDEX. A Work of Reference for Medical Practitioners. 1889. Seventh year. London: Wright, Bistal, Hamilton, Adams & Co. New York: E. B. Treat.

This is a valuable résumé of the year's progress in medicine, fully up to the times, and condensed to the minimum consistent with perspicuity.

The first part is devoted to *new remedies*, comprising the new drugs and new information added to our Materia Medica during the past year.

The second part aims to give all the new points with respect to treatment that have been offered in the same time. The diseases are arranged alphabetically and can be turned to in a moment.

Besides containing a compilation of the latest literature on the different diseases, the value of this part is increased by a number of new contributions on various subjects; such as Paralytic and Spasmodic Affections of the Throat, Sir Morell Mackenzie; Diseases of Women, J. W. Taylor; Electro-therapeutics, Kenneth Millican; Diseases of the Heart, James R. Leaming; Diseases of Bone, Syphilis, Jonathan Hutchinson, and many others.

The third part is devoted to miscellaneous information: New Inventions, Progress of Pharmacy, Dietic Novelties, etc. This work covers so wide a scope, and contains so much important matter, that there is not a physician to whom it would not prove of service.

SIXTEENTH ANNUAL REPORT OF THE SECRETARY OF THE MICHIGAN STATE BOARD OF HEALTH FOR THE YEARS 1887-88.

The report contains a number of interesting papers, such as: The Causation of Consumption; Time of Greatest Prevalence of each Disease in 1887; A Contribution to the Study of the Causes of Diseases; Relation of Certain Meteorological Conditions to Diseases of the Lungs and Air Passages as Shown by Statistical and Other Evidence; Report Concerning an Outbreak of Typhoid Fever at the State Prison, Jackson, Michigan, and the like; the whole forming a valuable addition to our knowledge of general health conditions.

DIGEST OF CRITICISMS ON THE UNITED STATES PHARMACOPŒIA. Sixth Decenial Revision (1889). Published by the Committee of Revision and Publication of the Pharmacopœia of the United States of America. Part I. New York, 1889.

This is a paper bound pamphlet of 189 pages, containing part of the criticims, corrections and suggestions relating to the last pharmacopœia. These have been collected with great care by a specially appointed competent man, and are intended mainly as a basis upon which to construct the next pharmacopœia.

SMALLPOX has broken out in Wilkesbarre; supposed to have been imported from Nanticoke.

Gleanings.

Surgical Diagnosis by the Teeth.—Referring to pyorrhœa alveolaris (Riggs' Disease), a condition in which the gums recede and non-carious teeth are shed, the author Jonathan Hutchinson pointed out that an analogous disease—sycosis—affects the hairs, in which a suppurative inflammation attacks the hair follicles and causes the hairs to drop out. Similarly the nails are in rare cases thrown off by reason of sycosis affecting their matrices. Sycosis of the beard, of the eyelashes (misnamed tinea tarsi, since no cryptogam exists), one and all have a similar pathogenesis, viz., a contagious inflammatory suppuration, the pus being carried from hair to hair and exciting fresh foci of suppuration. Although often occurring in weakly subjects, it was not necessarily confined to these; indeed, he regarded these forms of sycosis as local, and not constitutional conditions. The treatment seemed to lend color to this theory, for while tonics and general remedies did not ameliorate the disease, local epilation never failed. Comparing sycosis with pyorrhœa alveolaris, the lecturer insisted that the local inflammatory theory explained all the conditions. The purulent depots at the gum margins of the teeth infected one the other, and so the disease gradually spread.

Materials used for Stopping Teeth.—Without for a moment disparaging the value of amalgams as a stopping material, Mr. Hutchinson believed that in some rare instances they were the cause of intractable and irritable sores upon the lips, gums and cheeks. He spoke simply as an observer, not knowing the chemical composition of these stoppings, many of which, he was told, were secret preparations; but he had certainly seen ulcers which refused to yield to treatment disappear after the removal of discolored amalgams. He had always been careful to eliminate the probability of roughness of the stopped teeth being the cause, and had never seen ulcers where gold fillings had been employed. He quoted a case of an American physician who presented a number of ulcers which several surgeons had pronounced syphilitic; the patient, however, stoutly maintained that he had never had syphilis or a symptom of it, and all his children were perfectly healthy. Mr. Hutchinson, finding that he had several amalgam fillings, which had been inserted some years before in America, ordered their removal, which, being done, the ulcers rapidly disappeared.

Syphilitic Teeth.—Mr. Hutchinson said he had little new to say on this subject. The notched incisors were now generally admitted as evidence of hereditary syphilis. The upper centrals are the *test* teeth, and in no single instance had they misled the lecturer; but the markings on other teeth might be misleading, as they were often caused by the mercury given as a remedy for the syphilis, and were not due to the syphilis itself. In the great majority of cases of hereditary syphilis the markings on the central incisors are present, but not always so. Of several members of the same family one or two might have the characteristic teeth, while the others escaped. He wished to draw attention to two points of clinical observation: 1. In all cases where interstitial keratitis occurs there are found malformed teeth, and those who have the *test* teeth characteristically marked have suffered from interstitial keratitis. 2. Children who show signs of hereditary syphilis in the shape of phagedænic affections of the throat have no peculiarity of the teeth, and do not have interstitial keratitis.

The teeth affected by stomatitis, whether mercurial or other, were often mistaken for syphilitic teeth. Mercury given in infancy set up inflammation of the tooth sacs, and so led to deformity of the enamel. The test teeth in these cases are the first permanent molars, which might be compared with the premolars. Lamellar cataract, so commonly associated with stomatitic teeth, was due to convulsions. In adult life the presence of mercurial teeth was an assistance. Often the smallest doses of mercury would in these cases produce salivation, and the teeth revealing the idiosyncrasy would warn against its incautious use. The correlation of dental defects with errors in other structures had been brought before the Society by Mr. Moon. Rat-like teeth were due to suppression of lateral denticles, and were often associated with micro-ophthalmos and deficiency in hair. Skin defects, however, are not always accompanied by tooth lesions. Referring to dentition in rickets, Mr. Hutchinson deprecated speaking of any definite rachitic teeth; the disease attacked the teeth as it did other structures.

The value of considering the teeth lay in answering the question, not, are the teeth present, but rather how and why did the teeth go? Some constitutional conditions would affect this, or in some cases local disease, as in pyorrhœa alveolaris. Again, tartar causing gum absorption often ran in families. In some cases it was due to excessive salivary secretion. The lecturer did not consider gout, as such, produced any typical teeth. As long ago as Graves, tooth grinding had been shown to be common among the gouty, and this practice led to wearing down the teeth.—*Press and Circ.*

Disorders of Menstruation.—A. F. Currier, M.D. (*American Lancet*), in summing up a paper on this subject, says: "All these facts tend to show that the monthly congestion in woman is not local, but general, or at such times, that the vascular tension is so raised that vessels which are near the surface are much more liable to rupture than under ordinary conditions of tension and pressure."

Treatment of Aneurisms.—W. L. Rodman, M.D. (*American Practitioner and News*), concludes a thoughtful paper on Treatment of Idiopathic Aneurisms by Compression, by saying: "After reviewing the statistics of ligation and compression, I am forced to one of two conclusions: either surgeons in general do not appreciate the enormous fatality after ligation, or else they discredit the virtues of compression. Otherwise, how explain the fact that men go along doing an operation which statistics show is wholly unjustifiable except in the rarest instances?"

MORIARTY (Indian *Medical Gazette*), recommends bichloride of mercury and cannabis indica for dysentery.

L. M. MAUS, M.D. (New York *Medical Journal*), gives the history of a case of pregnancy extending to three hundred and thirty-four days.

EXTRAORDINARY SIZE. — H. A. Cooper, M.D. (Kansas City *Medical Record*), reports attending the confinement of a woman who gave birth to a child weighing 16½ pounds.

CUFF SPLINT.—J. E. White, M.D. (Canada *Practitioner*), describes a new splint for Colles' fracture, which he calls a "cuff splint," and for which he claims several important advantages.

CARDONI, of Florence, has found in the secretions of acute coryza the *staphylococcus pyogenes*, *staphylococcus aureus et albus*, the *diplococcus* of Fränkel, and the *pneumococcus* of Friedländer.—*The Microscope.*

ANTIPYRETIC.—J. R. Boyd, M.D. (Kansas City *Medical Record*), discusses the actions of the different modern antipyretics, and holds that saticylate of ammonium is the most satisfactory. He begins with grs. x every two hours.

TREATMENT OF GONORRHŒAL OPHTHALMIA.—Dr. Grandclement, of Lyons, France, advises to cauterize the conjunctiva every twelve hours with a 2 per cent. solution of nitrate of silver, and every hour to thoroughly and completely wash out the conjunctival sac with a solution of corrosive sublimate, 1–1000.—Lyons *Medical.*

PUERPERAL ECLAMPSIA.—Day (N. O. *Med. Jour.*), reviews the theories of eclampsia which attribute it to toxæmia, and finds them less satisfactory than Meigs' hypothesis of cerebro-spinal hyperæmia. Blood-letting, prompt, free, and full, is, therefore, placed at the head of the list of remedies, followed by chloroform, chloral, and rapid delivery.

TYPHOID FEVER.—At the meeting of the Medical Society of North Carolina the chief topic of discussion was typhoid fever. A full report will be found in the North Carolina *Medical Journal.* Dr. Broughton states that he has employed the sulpho-carbolate of zinc in two-grain doses, with the best results, not only in typhoid fever, but in all cases where the source of infection is from a germ generated within the gastro-intestinal tract.

TERTIARY LESIONS.—Blanc (N. O. *Med. Jour.*), mentions several important characteristics of the late syphilides. These are the clear-cut ulcer, the pyramidal tubercles accounting for the undermined edges, with healthy skin surrounding. The deposit is not long stationary; it must resolve, ulcerate, or cicatrize. The process spreads at the margin by the formation of new tubercles, giving the growth a serpiginous form, with crescentic or kidney-shaped patches, never geometrically complete.

CONGENITAL TETANUS.—Shaw (St. Louis *Med. and Surg. Jour.*), records a case of congenital tetanus. He gave one grain of chloral, five grains of bromide of potassium, and five minims tincture of asafœtida by enema, every two hours, so that during the first two days sixty grains of chloral and one hundred and fifty of bromide were given. The child's condition then warranted an increase of the interval between doses to three hours, and this was continued two days longer. The child recovered.

J. D. ELY, M.D. (*Medical World*), advocates the following for varicose ulcers:

℞.—Bismuth. subnit. . . . . ʒss. to ʒj.
Iodoform . . . . . gr. x to xx.
Cosmoline . . . . . ℥j.

Add listerine—which is an efficient compound to cover the odor of the iodoform, as well as being otherwise useful—a sufficient quantity. Mix, spread on soft cloth and apply to the ulcer, after cleansing it with carbolic or castile soap and water, and renew it night and morning.

RECOGNIZING the importance of aspirating the brain in cases of abscess or cyst, Souchon (N. O. *Med. Jour.*), recommends substituting the drill for the trephine for penetrating the skull. He has drilled holes through the skulls of several dogs, and through these capillary orifices has plunged large-sized hypodermic needles in various directions through the brain, without any untoward symptoms ensuing. This work could be best done by using the surgical engine.

ELECTRICITY IN CANCER.—J. I. Parsons, M.D. (*British Medical Journal*), details the history of four patients with cancer, whom he has treated with powerful galvanic currents locally applied. The *modus operandi* in each case was as follows: The patient was anæsthetized and an interrupted voltaic current passed through the tumor and all the tissues for some inches around it, by means of fine insulated needles, so as not to injure the skin. A battery of seventy cells with an electro-motive force of one hundred and five volts was used; and beginning with ten milliamperes the strength was gradually increased to six hundred, and flashed through the growth in every direction from fifty to one hundred times, according to circumstances, carefully watching pulse and respiration the while.

Three of the cases were carcinoma of the breast. The first was a rapidly growing scirrhus of seven months' duration; the second was a scirrhus of a year's duration, and the third a recurrent scirrhus of the same duration, having come back one year after excision. In two of these cases there was much pain. The fourth case was a painful and fast-growing epithelioma of the cervix uteri. Three of the cases were operated on for the first time August 23, September 26, and November 12, respectively, 1888, and the fourth January 13, 1889. Electricity was applied from one to four times in the different cases, and the history of each since has been total absence of pains and an apparent entire stoppage of the malignant growth. Not the least interesting feature is the fact that the patients were able to be up and about the day after the operation.

HARRIS (*British Medical Journal*) reports a case of pulmonary abscess which was cured by incision and drainage.

INGROWING TOENAIL.—Joseph (*British Medical Journal*) recommends the removal of the soft tissues covering the buried nail; believing that the latter is not at fault.

This was Pancoast's teaching twenty years ago.

MOORE (*Maritime Medical News*) recommends external friction and pressure during labor, in cases of uterine inertia, where the abdominal muscles are weak and relaxed, and in anteversion of the uterus; in fact, in the cases which call for an oxytoxic.

BROWN (*Maritime Medical News*) reports ten cases of orchitis, out of twenty consecutive cases of mumps. In nine the orchitis occurred on the side on which the parotitis first subsided. One was a double orchitis. Benefit was derived from rest in bed with the testicles supported.

EPILEPSY.—The time has come when we must recast our stereotyped definition of epilepsy as a disease characterized by sudden unconsciousness, etc. The epileptogenic zone is not confined to the psychomotor area, but epilepsy must start within it, or be arrested within it, or it may begin and end in the fasal ganglia. But wherever it may begin or end, if the lesion causing it is wholly within the motor area, consciousness need not necessarily be involved, and its loss, therefore, need not be regarded as an essential symptomatic evidence of the existence of epileptic disease.—*Hughes, Alienist and Neurologist.*

PURPURA: MALARIAL OR CINCHONAL.—King (*Southern Clinic*), reports a case of purpura hemorrhagica following the administration of quinine and antipyrin for a fever supposed to be malarial. The patient died. Dr. King attributed the outbreak to malaria, but there is more evidence in favor of the causative action of quinine. This is rendered more probable by the failure of that drug to relieve the other symptoms. Iron, ergot, turpentine, and digitalis, calomel, morphine, and belladonna were also used without benefit.

FOR HYSTERIA.—Ewald (*American Lancet*) recommends the following prescription in hyperæsthesia, gastralgia, vomiting, and spasmodic manifestations of hysteria:

℞.—Hydrochlorate of morphine . . 0.20 gramme.
Hydrochlorate of cocaine . . . 0.30 "
Tincture of belladonna . . . . 5 to 10.00 grammes.
Water of bitter almonds . . . 25.00 grammes.

Ten to fifteen drops are administered in one hour. The physiological effects should, of course, be watched in order that the doses may be modified, or suspended if advisable.

Medical News and Miscellany.

GURJUN OIL is said to cure leprosy.

QUARANTINE examinations are to be made at the Lazaretto on and after June 1.

DR. S. B. KNIGHT has been Superintendent of the Episcopal Hospital for thirty years.

DR. BROUSE, lately of Reading, is not dead, but alive and practising at Oklahoma City.

THE Philadelphia Medical Mission treated 3220 cases last year, and held 1017 meetings.

A FAMILY in Stamford, Conn., is said to have fourteen children down with scarlet fever.

THE Board of Health has forbidden the use of wells along Shur's Lane, which now pollutes the Schuylkill.

ST. LOUIS druggists now use the microscope largely in their business. This is some of Frank James' good work.

HAIR'S asthma cure is said to be made from a prescription of Prof. Bartholow's, upon which Dr. Hair has made over $300,000.

A FULL beard and six feet of stature are said to be essential to the success of the physician. Brains come in a good distance down the scale.

FOURTEEN of the buildings of the Stanford University in California are about completed. The dormitory will accommodate two hundred students.

AT the University Hospital, John Mumma had his trachea opened for the removal of a tooth, but the operator failed to extract the foreign body.—*Record.*

THE schools in Trimble, Miss., have been closed on account of the prevalence of hydrophobia, and men have been engaged to kill all dogs found on the streets.

A MAN named Ferro died on the operating table, at the Philadelphia City Hospital, from the effects of the ether. Dr. Ransley was operating for hip-joint disease.

THE Home for Incurables, one of the most successful charities ever started in Philadelphia, received about $25,000 in legacies and gifts during the past year.—*Times.*

A HYDROPHOBIC mule kicked a Hatboro' man. An alleged "mad-dog doctor" confined the man to his room for two weeks with little food and no water. The man got well.

THE couveuse at the Woman's Hospital is said to have saved four infants' lives in the past three months. A new incubator has been ordered from Paris which will hold three babies at once.

A CASE of Cæsarean Section was down on the bills at one of our city clinics the other day, but the child wouldn't wait, and came into the world by the usual route, before the clinic day arrived.

NETTER holds that patients who have recovered from pneumonia are dangerous to their friends for many years subsequently, as living pneumococci may be found in their saliva. This explains the frequent recurrence of the disease.

WHO is to take Keen's place at the Woman's Medical College?

If Dr. Goodman could be induced to leave New York, he would be an admirable man for the position.

THE Camden County Medical Society held its annual meeting at Gloucester. Dr. W. H. Iszard, of Camden, presided. Officers elected: W. A. Davis, President; H. H. Davis, Vice-President; E. L. B. Godfrey, Secretary; A. Mecray, Treasurer.

THE communication of disease from domestic animals to man is now the subject of investigation. The list of diseases known to be communicated in this way includes glanders, trichinosis, tuberculosis, and, probably, tetanus, diphtheria, and scarlatina.

HOW IT LOOKS TO A MAN UP A TREE.—Too many doctors spoil the broth, and the youngest one tumbles into it head foremost. Garfield might have been alive to-day if he had been attended by one single-purposed country doctor, instead of a squad of inharmonious wiseacres.—*Record.*

THE Maryland State Board of Health desires to coöperate with other State Boards in securing the passage of a law prohibiting the transportation of the bodies of persons dead from smallpox, cholera, leprosy, typhus or yellow fever: and the proper encasing of those dead from diphtheria or scarlatina.

A NEW weekly medical journal is announced to appear in St. Louis during the present year. The business management will be directed by a publisher well known in Chicago and St. Louis, who will spare neither labor nor money to make the undertaking a success. The editorial staff is not yet announced.

SIX deaths were reported, last week, from cholera infantum; two from cerebro-spinal meningitis; sixty-eight from phthisis; five from diphtheria; five from erysipelas; five from scarlatina; seventeen from typhoid; thirty-two from pneumonia; six from measles; one from purpura, and seven from whooping-cough.

IT is well known to the medical profession that when the editor of a daily paper is anxious to make an ass of himself in the most conspicuous manner possible, he usually selects some topic trenching upon medical matters. If he can pervert the facts in his attempt to disparage reputable doctors, and their ways, he waxeth hilarious. — *Western Medical Reporter.*

It may be received as a rule, that the habits and customs of a country are those which are best suited to it. Dr. Seymour has concluded that the houses of the Japanese, built of wood, are better suited to their country than the brick and stone structures erected there by Europeans. The wooden houses dry quickly. Infant mortality is very small among the Japanese.

THE WHY.

Germs in the air,
Germs in the sea,
Germs wherever one may be,
Germs and to spare
Growing in me,
German germs from Germany.

Whate'er we say
Or write or think,
Germs will wriggle in the ink.
On tongues they'll play,
And "culture" drink
From each minute cerebral chink.

—Boston *Medical and Surgical Journal.*

A NEGRO rushed into the University Hospital and, exhibited a blood-stained hand, exclaiming: "I've shot myself, and want my hand cut off!" Dr. Kirby procured his instruments, but when the wounded man saw the probe he made a dash for the stairs, and before any one could stop him, opened the door and ran up Spruce Street.—*Record.*

THE French show their good sense in providing ample conveniences for individuals in their cities. The Department of Public Comfort is equipped in a way that might well be imitated here. The establishment of urinals along our streets would not only conduce to the sanitary improvement of the city, but would be as potent a temperance promoter as the high license law.

IN the sixth report of the State Committee on Lunacy there occurs a statement which tells in brief the story of modern methods in the treatment of the insane. Out of a resident population of 5811 patients in the public and private hospitals of the State, but 52 were under restraint during the year. At the end of the year there were in public hospitals 585 more than at the beginning, in private hospitals 26 less, in almshouses 310 less, and two more in jails.

A RAPID FLIGHT.

A lie
Will fly
On wings of light
And leave a dismal trail,
While truth,
Forsooth,
Would lose the fight,
In racing with a snail.

—From the Danville *Breeze.*

COUNCILS are asked to relieve the city hospitals of the burden of gas bills. Of the funds contributed by the public to support these charities, 3 per cent. goes to pay for gas; and as under Director Wagner's management the Gas Works showed a profit of over half a million dollars last year, the city can well afford to donate the gas used by the hospitals. There is much force, however, in the Director's objection, that free gas to the city departments has led to extravagance in its use, and we would suggest that the donation of gas to the hospitals be limited to the amount used during the preceding year, any surplus used over this quantity to be paid for. In case additions to any hospitals are made the amount of free gas allowed could be increased proportionally.

THE corporators of the Philadelphia Polyclinic and College for Graduates in Medicine recently elected the following physicians to membership: Traill Green, Easton; J. L. Stewart, Erie; Hiram Corson, Norristown; John F. Carpenter, Pottsville; William Varian, Titusville, and R. Davis, Wilkesbarre. All of these are ex-presidents of the Medical Society of the State of Pennsylvania.

THE Children's Seashore House, at Atlantic City, will open on June 5. There is to be a new department for girls between fourteen and twenty years of age. This is a most useful charity, and deserves public support. If each of our readers would send $5 to Dr. Bennett, at the institution, a great increase in his power of doing good to the little ones who need sea air, would result.

THE printer cut down the appropriation made by the Legislature to the Medico-Chirurgical Hospital from $50,000 to $5000. Fortunately, the larger figure is correct. The Hospital is taking measures to raise an equal sum by subscription, as the plans for the contemplated rebuilding require $100,000, and the Trustees deem it wiser to carry out the original plan instead of making expensive alterations which would not be permanent.

THE charges of cruelty to patients in the Insane department of the City Hospital are to be investigated by the proper authorities. Whether the charges are substantiated or not, these investigations are generally productive of benefit, in refreshing the minds of attendants as to their proper relations with their patients. The natural impulses of man tend more frequently towards the acquisition of power and the exercise of authority than to mercy and loving kindness. Every safe guard should be thrown around the rights of those who are themselves helpless.

CHANGES IN THE MEDICO-CHIRURGICAL FACULTY.—Prof. Woodbury resigns the Chair of Materia Medica and Therapeutics, and becomes Honorary Professor of Clinical Medicine.

Professor Atkinson becomes Honorary Professor of Sanitary Science and Pædiatrics.

Prof. Shoemaker has, by a unanimous vote of the Trustees, been tendered the Chair of Materia Medica and Therapeutics in addition to that of Dermatology.

Dr. J. M. Anders has been elected Professor of Hygiene and Clinical Pædiatrics.

Dr. Spencer Morris becomes Lecturer on Differential Diagnosis.

LUNG EXPANSION.—We have seen men and women increase their lung power by five minutes exercise morning and night. Stand up straight on the balls of the feet, head thrown back, and inhale deeply, first inflating the lower part of the lungs, and then the upper. Then expire slowly, letting the chest sink first and then the lungs. Do this fifteen times, morning and evening, and our word for it, you'll spend less money on colds and catarrh.—St. Louis *Globe-Democrat.*

The injunction to "expire slowly" is unnecessary, as the victim will do it anyhow—of emphysema.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 14, 1889, to May 20, 1889.

HEGER, ANTHONY, Colonel and Surgeon; AINSWORTH, F. C., Captain and Assistant-Surgeon; and SKINNER, JOHN O., Captain and Assistant-Surgeon. By direction of the Acting Secretary of War, the above-named Board of Medical Officers will assemble at U. S. Mi itary Academy, West Point, N. Y., about June 1, 1889, to examine into the physical qualification of candidates for admission to the Academy and members of the graduating class. Par. 9, S. O. 108, A. G. O., May 10, 1889.

HORTON, SAMUEL M., Major and Surgeon; BILLINGS, JOHN S., Major and Surgeon; and SMART, CHARLES, Major and Surgeon. By direction of the Acting Secretary of War, the above-named officers are detailed to represent the Medical Department of the Army at the annual meeting of the American Medical Association to be held at Newport, R. I., June 25, 1889. Par. 15, S. O. 110, A. G. O., May 13, 1889.

APPEL, AARON H., Captain and Assistant-Surgeon. The leave of absence granted, by direction of the Secretary of War, in S. O. 38, April 16, 1889, Division of the Missouri, is extended twenty days. Par. 2, S. O. 114, A. G. O., Washington, May 17, 1889.

STEPHENSON, WILLIAM, Captain and Assistant-Surgeon. Leave of absence for four months, by direction of the Secretary of War, with permission to go beyond sea, is granted. Par. 15, S. O. 114, A. G. O., Washington, May 17, 1889.

EHERT, R. G., Captain and Assistant-Surgeon; MOSBLEY, E. B., Captain and Assistant-Surgeon. Leave of absence for six months, by direction of the Acting Secretary of War, on Surgeon's disability, is granted. Pars. 5 and 6, S. O. 109, A. G. O., May 11, 1889.

TESSON, LOUIS S., Captain and Assistant-Surgeon. Is relieved from duty, by direction of the Acting Secretary of War, at Waterrhit Arsenil, N. Y., and ordered to Fort Sidney, Neb. Par. 9, S. O. 109, A. G. O., May 11, 1889.

GORGAS, WILLIAM C., Captain and Assistant-Surgeon (now on duty at Fort Barrancas, Fla.). Will report in person to the commanding general, Department of the Missouri, for temporary duty with troops in the field. Par. 1, S. O. 112, A. G. O., Washington, May 15, 1889.

GORGAS, WILLIAM C., Captain and Assistant-Surgeon. Will accompany the command from Fort Barrancas, Fla., and proceed with Battery H., Second Artillery, to Fort Adams, R. I., and to return to his proper station on completion of this duty. Par. 5, S. O. 108, Headquarters Division of the Atlantic, Governor's Island, N. Y. City, May 13, 1889.

RAFFERTY, OGDEN, First Lieutenant and Assistant-Surgeon. Is granted leave of absence for one month. Par. 3, S. O. 29, Headquarters Department of Texas, San Antonio, Texas, May 13, 1889.

JEFFERSON, R. KEAN, First Lieutenant and Assistant-Surgeon (Fort Robinson, Neb.). Leave of absence for one month, to take effect between the 1st and 15th of June, 1889, is hereby granted, with permission to apply at Headquarters, Division of the Missouri, for an extension of fifteen days. Par. 2, S. O. 48, Headquarters Department of the Atlantic, May 13, 1889.

Changes in the Medical Corps of the U. S. Navy for the week ending May 18, 1889.

WHITING, ROBERT, Passed Assistant-Surgeon. Ordered to the Receiving-ship "Minnesota."

HARMON, G. E. H., Surgeon. Detached from the Naval Academy, and ordered to the "Constellation."

LOUNDES, C. W. F., Assistant-Surgeon. Detached from Naval Academy, and ordered to the "Constellation."

ARNOLD, W. F., Assistant-Surgeon. Detached from "New Hampshire," and ordered to the "Pinta."

RUSH, C. W., Passed Assistant-Surgeon. Detached from "Pinta," proceed home and wait orders.

MCCLURG, W. A., Surgeon. Ordered to the Bureau Medicine and Surgery.

STILT, E. R., Assistant-Surgeon. Detached from Bureau Medicine and Surgery, and ordered to the "Newhampshire."

ECKSTEIN, H. C., Surgeon. Ordered to the Marine Rendezvous, Philadelphia, Pa.

BRADLEY, M., Medical Director. Detached from Marine Rendezvous, Philadelphia, Pa., and continue on special duty, Philadelphia.

RUTH, M. L., Surgeon. Granted another year's leave.

A REVIEW OF THE CASES OF TUBERCULOSIS

WHICH TERMINATED IN DEATH IN THE FIFTH WARD OF THE CITY OF PHILADELPHIA DURING THE YEAR 1888.

BY LAWRENCE F. FLICK, M.D.

BECAUSE of the confusing and indefinite nomenclature of tubercular diseases, and because, also, of the incompetence to make a diagnosis of some physicians who practise medicine, the deductions drawn from Board of Health reports cannot be accepted with any great degree of confidence. Nevertheless, with a disease from which there are as many deaths as there are from tuberculosis, we ought at least to arrive at general truths by careful topographical studies of such reports, and it is with the object of throwing some further light upon the questions of the contagiousness of tuberculosis that I present this brief paper.

The Fifth Ward of the city of Philadelphia has an area of .321 square miles, has a population of about 16,000, and contains in the neighborhood of 3500 houses. The population consists mostly of poor people, is about 20 per cent. colored, and has in its make-up foreigners of every description and nationality; but in no part of the ward can there be said to be great overcrowding.

During the twenty-five years preceding 1888, about fifteen hundred deaths were returned from the Ward under the various nomenclatures for consumption of the lungs and bowels, and such other nomenclatures as have the word tubercular attached or have that word for their basis, and they occured in about nine hundred and fifty houses, thus infecting about 30 per cent. of the houses in the ward. Deaths returned under the heading of marasmus and other nomenclatures, and which were really due to tuberculosis, are not included in the fifteen hundred; hence, 30 per cent. may be looked upon as too low a representation of the number of infected houses, but inasmuch as deaths from such diseases occur largely in the same houses as deaths from tuberculosis of the lungs, as will be seen from the report for 1888, their exclusion in determining the number of infected houses cannot materially alter the result, and 30 per cent. may be accepted as proximately correct. I have selected twenty-five years as the most remote period to determine the infection of a house by, for two reasons: First, because a house may retain its infection for a long time by intercurrent cases, which may get well, may move away and die somewhere else, or may die and be returned under some false nomenclature; and, secondly, because the more remote the period the stronger the emphasis on the non-infectedness of those houses which are set down as such.

During the year 1888, there occurred in the Fifth Ward of the city of Philadelphia 103 deaths which

may plausibly be ascribed to some form of tuberculosis. Of these, 60 were returned under the various nomenclatures for consumption, 17 under the heading of marasmus, 7 under that of meningitis, 3 having the word tubercular attached, 5 under that of hæmoptysis, 4 under inanition, 2 each under tabes mesenterica and consumption of the bowels, and 1 each under tuberculosis, general tuberculosis, chronic bronchitis, empyema, scrofula, and asthma.

Of the 103, 15 were returned from the residences of undertakers, 3 from the Consumptives' Home on Spruce Street, 1 from a lodge room, and 1 from the Almshouse. Of the cases returned from the residences of undertakers, 11 were cases of phthisis, 2 of marasmus, and 1 each of scrofula and general tuberculosis. The cases from the Consumptives' Home, the case from the lodge room, and the case from the Almshouse were all cases of phthisis. Four of the cases returned from the residences of undertakers died at the Almshouse, 2 at Pennsylvania Hospital, 1 at St. Mary's Hospital, 1 at St. Joseph's Hospital, 1 at the Consumptives' Home at Chestnut Hill, and 1 at Moyamensing Prison. Inquiries as to the dwelling places of these cases prior to their entry into the hospitals were attended with unsatisfactory results, but some of them, at least, lived outside of the ward.

Deducting the cases returned from the residences of undertakers, consumptives' homes, etc., 20 in number, from 103, the number returned from the ward, we have 83 cases which were reported from the residences in which they presumably died. Of these, 44 were cases of tuberculosis of the lung, returned under its various nomenclatures, 15 were returned as marasmus, 7 as meningitis, 5 as hæmoptysis, 4 as inanition, 2 each as consumption of the bowels and tabes mesenterica, and 1 each as tuberculosis, asthma, empyema, and chronic bronchitis.

Of these 83 cases I find that 48 were returned having died in houses which were infected, that is, houses in which a death from some form of phthisis, or some disease with the word tubercular attached, had occurred sometime within twenty-five years; and 35 in houses which were not infected, that is, houses in which no such death had occurred within twenty-five years. Of the cases which died in infected houses, 23 were returned as phthisis under its various nomenclatures, 10 as marasmus, 5 as meningitis, 2 each as tabes mesenterica, inanition, and hæmoptysis, and 1 each as tuberculosis, asthma, empyema, and consumption of the bowels. Of the cases which died in non-infected houses, 21 were returned under the nomenclatures for phthisis, 5 under that of marasmus, 3 under hæmoptysis, 2 each under meningitis and inanition, and 1 each under consumption of the bowels and chronic bronchitis.

Of the 23 infected houses from which a death from tuberculosis of the lungs was reported, 18 had had a death from tuberculosis in them within ten years, 14 within seven years, 12 within four years, and 8 within two years. Of the 10 infected houses from which a death from marasmus was reported, 9 had had a death from tuberculosis in them within ten years, 8 within seven years, 7 within five years, 4 within one year. Of the 5 infected houses from which a death from meningitis was reported, 2 had had a death from tuberculosis in them within ten years, and 1 within three years. Of the 2 infected houses from which a death from inanition was reported, 1 had had a death from tuberculosis in it within five years. Of the 2 infected houses from which a death from tabes mesenterica was reported, 1 had had a death from tuberculosis in it within one year. The infected house from which a death from consumption of the bowels was reported, had had a death from tuberculosis in it within three years. Thus it will be seen that out of the 48 infected houses in which deaths from tuberculosis occurred during the year 1888, 32 had had deaths from tuberculosis in them within ten years prior to 1888.

In only 5 of the 48 cases which were returned from infected houses during the year 1888, was the name before; and of these, 2 probably bore the relation of husband and wife to the person who had died in the house first.

About the 23 cases of tuberculosis of the lungs which were returned from infected houses, I was given the following information at the houses from which they were reported: 1. That 4 of them did not die in the house from which they were returned. Upon inquiry I was able to locate the place of death of 2 of these, 1 having died at a hospital, and the other having lived and died in an infected house. 2. That 8 of them had consumption before they moved into the houses in which they died. Of 3 of these I was able to discover the former dwelling-place, all 3 of which contracted the disease whilst living in recently infected houses.

About the 21 cases of tuberculosis of the lungs which were returned from non-infected houses, I was given the following information at the houses from which they were reported and by neighbors and friends of the diseased: 1. That 1 of them did not die of consumption, but was reported to have died of that disease for delicate reasons. 2. That 2 of them did not die in the houses from which they were returned. In both of these I was able to locate the place of death, and in 1 of them I found that the house was an infected one, that the person had lived there a year but that he probably had the disease when he moved there. 3. That 7 of them had had consumption when they moved into the houses in which they died. Of 2 of these I was able to discover the previous residence, and in both I found it to be an infected house. 4. That 2 of them had been associated with consumptives in their business. In neither of these cases was there any family history of consumption. 5. That 5 of them lived in lodging houses, where there was a constantly changing population, and that 3 of these were drinking people.

This information, I am sorry to say, even meagre as it is, is not very reliable. The fears, suspicions, and prejudices of many of the people from whom I sought it, prevented them from telling the entire truth and even lead them to misstate facts. I give it, however, as I got it, so that every one, with the entire picture before him, may draw his own conclusions.

Even the data which I took from the Board of

Health records I cannot endorse as entirely trustworthy. The custom of returning deaths from the place of burial instead of the place of death, the carelessness of undertakers in giving the numbers of houses and wards, and the indefiniteness of the nomenclature used by physicians, I am sure engendered mistakes which I have not in every instance been able to correct.

The moving about, from place to place, of persons suffering from tuberculosis ought likewise to be taken into consideration in drawing conclusions, where infected houses, so determined upon mortality statistics alone, form part of the premisis of the argument. To what extent such change of residence alters the actual percentage of infected houses, and, consequently, invalidates the conclusions based upon the facts and figures I have given must, of course, remain an unknown quantity, and must be approximately measured by every one for himself.

In spite, however, of all the sources of inaccuracy, which I have just mentioned, the figures which I have given, bearing upon tuberculosis in the Fifth Ward of this city for the year of 1888, point unmistakably to the fact that tuberculosis is not only contagious in the broad sense of that word, but that a house in which that disease has existed, remains a centre of infection for an indefinite time. Upon no other theory than this can a rational explanation be given of the fact that whilst less than one-third of the houses of the ward became infected with tuberculosis during the twenty-five years prior to 1888, considerably more than one-half of the deaths from tuberculosis during the year 1888 occurred in those infected houses. In as much as there were more than twice as many non-infected houses in the ward as there were infected houses, we should naturally expect a preponderance of deaths in non-infected houses. Why this great preponderance of death in infected houses?

The conclusion that houses once infected by tuberculosis, retain that infection for some time, is even more strongly borne out by individual cases than by the aggregate number of cases during the year. A death from tuberculosis occurred in a house on Gaskill Street in 1880. The family moved out and R. H. moved in. Was quite well when moved there. Was a travelling salesman and was away from home a good deal, but had his home there. In time developed consumption and died in 1888. L. M. lived in the house, in which she died, for many years. A person who was no relative of hers died from consumption in the house in 1887. She took the disease in a very acute form and died in 1888. H. M. suffered from chronic tuberculous diarrhœa and died from it during the year 1888. During that same year there occurred a death from marasmus in the same house. A death from consumption of the bowels was returned during January of 1888, from a certain house on Hurst Street; a woman who died from phthisis during September of the same year on Lombard Street, probably contracted the disease in that same house, as she lived there about that same time. During the latter part of 1887, a person died of phthisis in a certain house in the ward; during July, of 1888, a child nine months old, not of the same family, died in the same house from tabes mesenterica. During the month of September, 1888, there occurred 2 deaths in an infected house in the ward, 1 from marasmus in a child one year old, and 1 from meningitis in a child two years old. The house had had 3 deaths from tuberculosis within recent years, the most recent reported being 1885. In a house on St. Mary's Street a death occurred from consumption during the latter part of 1887; during July, 1888, a child seventeen months old died in the same house from marasmus. A woman is reported to have died from phthisis in a house on Union Street during the year 1888, from which no cases of tuberculosis had ever been returned before. The house is a lodging house, and she is said to have taken the disease whilst living there. A man who died in a non-infected house on Spruce Street during the same year, was found to have contracted the disease in the same house about the same time. A death from tuberculosis was returned from a house on Dock Street in 1882. J. C. moved into the house sometime in 1884; he contracted consumption and died in 1888. These cases are all taken from among those who died from tuberculosis in the Fifth Ward during the year 1888. By going back of that year, I could cite from my notes hundreds of equally striking cases illustrating the infectious etiology of tuberculosis.

Perhaps, one of the most interesting lessons to be learned from this inquiry into the relation which the deaths from tuberculosis in the Fifth Ward during the year 1888, bore to those from the same disease during the twenty-five years prior thereto, is that bearing upon marasmus and meningitis in children. It will be remembered that out of 22 deaths from these two diseases, 17 occurred in houses which had been infected by tuberculosis of the lungs and the bowels in adults. It would appear from this that marasmus and tubercular meningitis in children are apt to be concurrent with tuberculosis of the lungs and the bowels in adults; that is, where an adult is suffering from phthisis or consumption of the bowels in a house, the children of that house are prone to develop marasmus or tubercular meningitis, and that these diseases are not apt to become centres of infection themselves.

It is somewhat surprising that only 7 deaths were returned from the ward under the heading of meningitis for the entire year, and that really only 3 of those had the word tubercular attached. The number of cases of tubercular meningitis which I meet with in my own practice would lead me to believe that these figures do not correctly represent the relative frequency of the disease, and that in all probability many deaths which are ascribed to convulsions are really due to tubercular meningitis. I have within the last year seen 4 deaths from tubercular meningitis in children, 3 of which occurred in houses in which there was a case of phthisis in an adult.

It is greatly to be regretted that our nomenclature of tubercular diseases is not more definite and more uniform than it is; for until it becomes so, statistical and clinical study of the disease will necessarily remain difficult. We cannot hope, however, to make much progress in this direction until the etiology of tuberculosis is settled, and until precise knowledge

upon the subject will be dispensed from every seat of medical learning. It is with the desire of hastening that day that I present this statistical analysis, if I may so call it, hoping thereby to stimulate others to enter this promising field of study.

Many interesting deductions, besides the few which I have made, might be drawn from the figures which I present, and many criticisms made upon the practical operation of our sanitary laws, as a legitimate part of this paper, but it would lead to subjects which would, in themselves, furnish material for cumbersome papers. I will, therefore, for the first rest content with stating the facts and calling attention to a few of the most striking conclusions which grow out of those facts.

CONSTIPATION, CAUSE AND TREATMENT.

By A. W. McKINNEY, M.D.,
HUTCHINSON, KAN.

WE are well aware that in attempting to write a paper on this subject we enter a broad field. But as we are not as versatile as we would be, we shall occupy only such a portion of the field as may come within the narrow range of our vision.

The causes of constipation, according to our own observation and that of our authors, are many; but to our mind there is one cause greater than all others, that cause is habit, and we shall consider our subject from that standpoint.

We regard constipation more a condition than a disease. Anatomists, in describing the alimentary canal, consider it by divisions, and call the lower division the rectum. They also inform us that the lower portion of the rectum is conveniently guarded by a set of muscles called the sphincters. Those muscles are directly under the control of the will. The genus Homo, however, is the only animal that exercises that power to its own detriment.

Physiologists, in describing the functions or office of the rectum, tell us that when an amount of effete matter or undigested food reaches the rectum in quantity sufficient to produce moderate distention, the desire for defecation is produced, and that it (the rectum) is very sensitive to this distention; but, as in many other localities, this natural and wisely ordained sensitiveness may be overcome or blunted to the extent of tolerating the presence of substances that would otherwise cause unpleasant sensations. This educated (so to speak) toleration is the constipation of which we purpose to speak.

The merchant or the clerk is engaged with a customer when the alarm is sounded and the action is deferred.

The seamstress or the housewife feels the call, but more frequently defers on the account of innate (false) modesty. We believe the average woman would keep the sphincters in action for an entire week rather than be conscious that some man saw her on the way to the commode. The consequence of this procrastination are dried fæces scybalæ, congested vessels and hemorrhoids, and one or all are upon us before we are aware of it.

Treatment.—When an individual who has strayed from his home over a strange road, desires to return, his best and most certain plan will be to retrace his steps, and as nearly as possible travel over the same road he came.

Constipation caused by habit must be cured by habit mainly, and if a patient be brought to see and realize the importance of habit, the condition can be relieved with but little medication.

In our treatment of such cases, we require our patient to pledge himself to carry out our instructions faithfully and persistently. We ask him to elect his hour for defecation, which may be chosen to suit his convenience (the morning hour is preferable), and when once chosen must not be changed.

We direct a diet easily digested and laxative in its nature, with ripe fruit in its season, and just at mealtime to sip a cup of hot water, and encourage him to make free use of water between meals. Our patient pledges his obedience and elects his hour, say 8 A.M. We say to him: "You must get out of bed at 7, perform the morning ablution, or take a bath, drink a glass of cold water, in which two or three times a week you must dissolve one-half or one teaspoonful of common table salt. Then do your chores, if you have any to do. If not, take a brisk walk of half a mile and return, eat your breakfast (don't forget the hot water) and promptly at the elected hour start for the commode. Don't start fifteen minutes before or fifteen minutes subsequent, but exactly on time, and when you do start, start with a determination that some one must defecate, and that some one must be yourself, and no other person or animal. On your arrival at the commode lay aside your worldly affairs and attend strictly to the business for which you come. Do not take a paper, a book, or a cigar, but concentrate your mind on and use your will-power in the endeavor to overcome the condition you have carelessly and inadvertantly allowed yourself to get into.

When seated on the commode call into exercise the expulsive power of the abdominal muscles in a gentle way. Do not strain or make a Herculean effort, but repeat this action several times, and if you do not succeed, try again next day, and every day until the seemingly lost function has been restored, as it surely will. Confirmed constipants may need some therapeutive medicating as a starter, but with caution, aperients now and then, cathartics seldom or never. A seidlitz or a dose of cascara administered so as to act about the elected hour, but what is better a small enema, warm, and of sufficient quantity to slightly distend the rectum. This will be beneficial in more ways than one. The hardened fecal mass, if hard, will be softened. The warm water will attract the blood to the rectum. The distention will, to a great extent, stimulate the lost sensibility, and above all will tend to concentrate and impress the mind of the patient as to the object of the hour. The enema should be used just before going to the commode or after arrival. We endeavor to impress our patient with the danger of either aperients, cathartics, or enemata, and interdict their use only at such times as the general system or local parts become restive. We try to

impress upon our patients a persistent and continuous effort in the direction advised. We try to impress him as to the fact that habits are easily formed, but hard to change when once formed—that patience and perseverance are commendable virtues, but are in cases of this kind indispensible to success. Although we have passed the point of order, we will return to it and give another cause of constipation, and in so doing call attention to a very important factor in the treatment as well as the prevention.

The Construction and the Condition of the Commode or Water-closet.—Dr. Graham was in the neighborhood of the truth when he said: "The man who can construct a comfortable privy confers a great boon on humanity. We all realize the mutual impressions produced by pictures, as did he who issued the emancipation proclamation." Whoever builds a residence, builds his privy last, and out of the refuse scraps of lumber left from the building, and all the carpenter can do is to construct a something that will shield a man or a woman from public view during the performance of a necessary act that modesty forbids being performed in public. In addition to the ill-construction, it seems that those who use them emulate each other as to who can pollute them most. When we are compelled to use the average privy, we feel like condoning the errors of the constipants, and do not blame them for dreading to visit that (should be pleasant, but generally loathsome) place.

A building of this kind should be constructed with a view to comfort. Should be warm, should be light, should be clean—in fact, every device should be resorted to, in order to make that locality pleasant when occupied. The approach should be guarded by an arbor or screen. The walls painted and embellished with pictures if you so desire. It is a matter of history that the Hunchback had a profusion of suggestive pictures in his marital chamber; and it is said that a London hotel-keeper, thinking to provoke an American guest, hung the portrait of General Jackson in the privy. Seeing his guest had just come from that locality, he inquired as to the propriety of displaying the portrait in such a seemingly ludicrous place. The American applauded his taste and good judgment. For said he; "If there is anything in the world that will assist and encourage an Englishman in the act of defecation, it would surely be the portrait of General Jackson." This may be a homely illustration. I hope it will not be considered a vulgar one, but it serves to illustrate our point that the surroundings have much to do with the perfect accomplishment of an act, the regularity and completeness of which has so much to do with the human comfort and health.

We have in our very imperfect paper tried to condense, and yet be explicit, in giving a general outline of the management of these cases so frequently met with. Each case must be treated on its own merits and the physician in charge must use his own judgment. If the reading of this paper will be the means of causing you to give more attention to this condition than you have heretofore, we shall have our reward.

REMOVAL OF EPIPHISEAL EXOSTOSIS OF HUMERUS.

(Read before the South Kansas Medical Society, at Wichita, May 14, 1889.)

By JAMES B. HUNGATE, M.D.,
CONWAY SPRINGS, KANSAS.

At the May meeting of this Society, one year ago, I verbally reported the case of J. A. L., male, aged thirty-seven, married, and the father of six healthy children. A few weeks prior to my report he had consulted me on account of a tumor near his right shoulder-joint. He stated at the time that he had first noticed its appearance about two years before, and that he had consulted numerous physicians who had failed to agree as to the nature of the growth, and advised a do-nothing plan of treatment for fear of opening the joint cavity, in case of its removal, which would in all probability result in a totally stiff joint, and possibly the loss of his life.

On careful examination I found an enlargement attached just below the anatomical neck, and between the greater and the lesser tuberosities of the right humerus, about the size of a small hen's egg. That it had its attachment to the bone was evidenced by the fact that it could only be rotated or moved in any direction except as the humerus was so rotated. The deltoid muscle covered it over, and when that muscle contracted could only elevate the arm to an angle with the body of forty-five degrees, because the bony growth came in contact with the acromion process of the scapula. Motion of any kind was limited as soon as the elbow was brought out of contact with the body. Moreover, the patient complained of a weakened condition and an aching of the entire arm, which, in a measure, incapacitated him for manual labor.

I stated to the patient and to this Society that the tumor was an exostosis, and advised its early removal under strict antiseptic precautions.

In Druitt's system of "Modern Surgery" we find the following: "But these operations are not to be undertaken without due forethought, for they may be followed by extensive inflammation and necrosis, or by suppuration into a joint; and in operating on an exostosis near a joint, the possibility of opening the synovial membrane should always be considered."

Billroth says: "These tumors occur almost exclusively on the epiphyses of the long bones; they are outgrowths from the epiphyseal cartilages, whence Virchow very properly calls them 'enchondrosis ossificans.' On their roundish, nodular surface there is a layer of beautifully-developed hyaline cartilage, about a line or a line and a half thick, which evidently grows partly in itself, partly peripherally from the periosteum or perichondrium, then rapidly ossifies toward the centre. The newly-formed bony mass itself is, from the start, most intimately connected with the spongy substance of the epiphyses, so that the hard tumor is immovably seated on the bone. From the nature of these exostoses they can only occur in young persons. According to my observations, tibia, fibula, and humerus are their most frequent seat.

"As regards epiphyseal osteomata, which might be termed ossifying chondromata, they, of course, cannot occur later than the twenty-fourth year. But

other exostoses also occur generally before the thirtieth year. Observations on this point are not numerous, as the disease is rare. The growth of epiphyseal exostoses ceases after the skeleton has completed its growth."

The same author further says: "The operation for exostosis consists in sawing or chiseling the tumor from the bone affected. But, as the latter is occasionally in the vicinity of a joint, the articulation might thus be opened; it is neither advisable nor necessary to undertake such operations unless the impairment of function be so great as to balance an operation dangerous to the joint and to life. I once allowed myself to be induced, by the entreaties of the patient, to remove such an exostosis on the lower end of the femur with a large mucous bursa. The patient died of septicæmia."

I could multiply quotations from Holmes, Ashhurst, and others, in support of the above grounds taken by the authors quoted; but hope I shall be pardoned for being so tedious, my aim being to show the dilemma I was in when I advised the operation in the case of my patient. My sole reliance and confidence in the success of the operation rested in the efficacy of antiseptic and aseptic surgery; therefore, I gave my advice fearlessly.

The patient presented himself for the operation on the morning of February 1. Dr. C. S. Monnett gave me valuable assistance and administered chloroform. I scrubbed the entire shoulder with flesh brush, using soap and bichloride water, after which I surrounded the parts with wet antisepticized cloths. A 1 to 1000 HgCl solution was kept playing over the field of operation during the entire time, from a fountain irrigator. Hands and instruments were dipped in an alcoholic solution of carbolic acid, and I made an incision immediately over the tumor. After cutting through the skin, superficial fascia, and deltoid muscle, I came upon the covering of the tumor, which I cut through and turned to either side. With my finger in the wound of operation I could distinctly feel the capsule of the joint, and carefully avoided injuring the same. I placed a small surgical chisel on the top of the growth and directed an assistant to strike it smartly and carefully with a mallet. The neoplasm readily parted company with the humerus after the third stroke. I carefully smoothed off where the base of the growth was, and removed several projecting points. The membrane that had covered the tumor was used then to cover the bare bone surface. Bleeding vessels we secured by torsion; iodoform was freely dusted over the cut tissues, a rubber drainage-tube was inserted, and the operation completed by suturing with continuous silk suture. Iodoformized bichloride gauze was used as a dressing, and the patient removed to his home.

The subsequent progress of the case was favorable in every particular, except that the patient on the seventh day tried to lift a bag of oats with his right hand to see what he could do. He succeeded in breaking open the line of union by first intention of the horizontal bar of the T, which now kindly healed by granulation, and leaves a moderately wide cicatrix. The temperature at no time exceeded 99⅘° F. There was not a drop of pus discharged from the cut, and but slight inconvenience of any kind from the operation.

I herewith exhibit the bony growth, which you will see is of spongy, cancellous bone tissue covered over with hyaline cartilage, and on observing the base of the tumor, a correct idea of the appearance of the connection between the humerus and the growth may be obtained.

The patient is now no longer inconvenienced by an unsightly deformity, is able to use his arm to perfection in his battle for bread to support his numerous family; is free from pain and uneasiness, and has received the highest possible good by the removal of an unwelcome intruder upon his peace and happiness.

The lesson I would teach, and that we should learn as surgeons, is that we should be independent thinkers, and ever remember that each case is a study in itself, and we are to bring to the solution of each problem a trained mind and look at the matter with surgical eyes, but to never blindly follow the *ipse dixit* of any author or set of authors, however great their reputation for skill and learning.

HUNTING THE GERM OF YELLOW FEVER.

By FRANK S. BILLINGS.

(Director of the Patho-Biological Laboratory of the State University of Nebraska.)

[Continued from page 80.]

IN the Comptes Rendus, Tome CV., p. 289, is an article: "Sur les formes bacteriennes qu' on recontre dans les tissues des individues morts de la fievre jaune," by Mons. J. B. Lacerda who says:

"*In all these preparations, without exception, I have found one bacterium exactly identical with that which Babes has already found in material sent him from here by me.*"[1]

The reader will observe that Lacerda says, "in all these preparations."

It would seem that Lacerda had given a description of his observations, exactly similar to that which follows, some years previous to the one here noted, for Babes says:

"At the same time (in which B. received material from L.) Lacerda sent a communication to the Academy of Sciences upon the parasites of yellow fever. But according to the drawings attached to this communication, we have convinced ourselves that he has been deceived, and that he has described filaments of vegetable tissue and pigment instead of these parasites."[2]

On the other hand, as Babes has described this organism, as well as illustrated it, in such a manner that we are enabled to recognize it sufficiently for comparison, and as Lacerda asserts that he has also found "in all preparations, without exception, one bacterium, exactly identical with that which Babes has already found," and as even Sternberg admits its existence in the tissues of such subjects, we have very conclusive evidence that it must be the patho-

[1] This material was taken from six different individuals.
[2] "Les Bacteries," p. 447.

genetic organism of that disease, even without the necessary conclusive experimentation upon man, which must be left out in such cases.

Lacerda's description is as follows:

"These bacteria are dispersed all through the substance of the liver and are found in cluster in the cells of the organ, and are profusely present in the capillaries of both the bile and blood circulatory systems. In the kidneys they are also found in the capillaries, the urinary tubes, and the convolutes of the Malpighian tufts, and in the lymphatic spaces."

"When sections of the liver are colored the bacteria take up the stain very unsatifactorily."

The above does not coincide with my own experiences, as I have found no difficulty in staining the organisms in the liver any more than in the kidneys, of which Lacerda says:

"But in the kidneys, on the contrary, they can be more easily stained and may then be studied in all their morphological details."

I cannot accept Lacerda's description of these details at all, as they do not describe the single organisms, and such description as he gives of dicho- and trichotomous division of the chains does not occur.

But to go on. He says:

"The bacteria invariably present themselves in chains, formed of a series of granules of approximately the same dimensions, being slightly elongated and cylindrical in form, the points of articulation of the granules being very solid, thus opposing the easy disintegration of the chains. When uncolored the granules are very refractive by reflected light."

"What distinguished this bacterium from all other known forms is its tendency to constantly present this ramified form! They frequently have a trifurcated stem with two lateral branches which leave the parent stem at a common point of origin, where they assume a curved course, the parent stem also developing at the same time. At another time they form long branches, one of which is nearly straight, while the other is someweat bent; the bent branch being dichotomous!!? In other cases there are two straight branches of approximately the same length, resembling the arms of a pair of open compasses at an acute angle. In still others, the ramifications are placed at right angles, having the appearance or form of a cross. There are others that scarcely have any indications of bifurcation, the two branches being much shorter than the other and curved in opposite directions. Again, we may see three ramifications of the same length extending from a common centre. The central granule of the primary stem, from which these branches extend, is often larger than those of the secondary formations, and presents a spherical rather than a cylindrical form. It is also often the case that the terminal granule of the branches is the largest and most spherical."

"I ought to add that in preparations of the blood I have found forms resembling the same, and I have no doubt that non-ramifying forms found in the blood and tissues are the result of accidental disintegration of the chains."

Examination of the Tissues from Dr. Lacerda, sent by Dr. Sternberg.

Liver.—Parenchymatous changes quite severe with an absence of the nuclei in many of the cells. Marked encroachments upon the parenchyma in all parts of the organ due to an increase in the connective tissue, most of which is more or less organized. In the vascular spaces the tissue showed very little cellular structure. The walls of the arteries and ducts being excessively thickened—especially the latter. In the parenchyma itself, are to be seen numerous round, almost transparent, hyaline looking bodies varying in size from that of the ordinary nucleus of a liver-cell to that of the cell itself. Many other cells have been transformed to a granulous detritus.

Kdineys.—Extreme degree of parenchymatous degeneration, the parenchyma of many of the tubes being one mass of granulous detritus, the nuclei being especially conspicuous by their almost entire absence. In other tubes the basement cells present distinctly visible nuclei, while the aforementioned detritus takes up the balance of the lumen. Hyaline casts are to be seen here and there in both transverse and longitudinal sections of the tubes. Diffuse centers of round-cell infiltration with marked abscence of parenchymatous structure in the same, are to be seen scattered through the organ. The Malpighian tufts are marked with the presence of occasional loops presenting a hyaline, more or less transparent, appearance characterized by the entire absence of anything resembling a nucleus. The Bowman's capsules are thickened as well as the walls of the capillaries and membrana propria of the tubes, with an occasional more or less circumscribed round cell infiltration scattered here and there between them.

Microscopic Examination of above Tissue for Germs.—Both smear-preparations and sections are marked by the presence of a most plentiful representation of an ovoid germ with distinct belted appearance and sharply-colored pole-ends, the normal length being twice as long as wide, some individuals are three or four times longer than wide, this increase in length being entirely due to an increased amount of the afore-mentioned uncolored substance. In some instances two, three, or four of either of the above described forms are to be seen attached together forming short chains. Such a short chain is at other times composed of both of these forms united together, there being more of one and sometimes more of the other in the same.

The organisms appeared, as this variety always does, in the sections of organs, some of them end on, when they looked like cocci; beside these would be others lying horizontally, which presented their complete form, the colored pole-end and clear center being distinctly visible; in many localities they were united in pairs, while many of the liver cells contained large numbers of them. Here and there one would find a capillary embolus made of nothing else; here they frequently grew in filaments of considerable length, large clusters of such being present; occasionally single filaments were to be seen in capillaries which the section had cut horizontal to their course, but in general, except in the embolisms, they were seen in pairs or groups of three members. Capillary

embolisms were more frequent in the kidney than in the liver.

No other micro-organisms present, notwithstanding numerous sections of the same tissues were subjected to very many tinctions used in this work.

The result seems to have had a much more convincing effect on my mind than on that of Dr. Sternberg, for as we see he still is of the opinion that "there is no satisfactory evidence that any one of these microörganisms is the veritable infectious agent in the disease under consideration."[1]

I will not enter upon the discussion of this point at this moment, but will at once proceed to detail observations made upon pieces of material from six other equally "undoubted cases" of yellow fever, which were procured for me in Havana, Cuba.

It required the overhauling of a very large amount of red tape in order to get this material from Havana, and were it not for the sincere kindness of Dr. John B. Hamilton, the efficient Surgeon-General of the United States Marine Hospital Service, at Washington, I should have been unsuccessful. Dr. Hamilton recommended me to Dr. D. M. Burgess, Inspector for the above service at Havana. The difficulties in the way of procuring such material are so well set forth, by Dr. Burgess in the following letter, that I think it not inappropriate to introduce it here.

HAVANA, CUBA, July 4, 1888.

DR. JOHN B. HAMILTON,
Surgeon-General, Marine Hospital Service.

MY DEAR DOCTOR: I received your communication in which you informed me that you had referred Dr. Frank S. Billings, of Nebraska, to me for pathological material from yellow fever patients, and in due time a letter of instructions came from him. Since then I have been improving every opportunity to get the desired material; but this year it is rather slow work, as very few persons have died outside the Military Hospital. The law here is to the effect that autopsies shall not be made until eight hours have elapsed after the death of the subject. At that time decomposition in those dying of yellow fever, and, of course, in hot weather, is well under way, and putrefaction organisms abound everywhere. If one happens to have the necessary influence with the Captain-General, etc., etc., and brings it with him here, autopsies can be got sometimes at the Military Hospital for military reasons, etc., pretty soon after death; but these are *exceptional* instances, and by *no means* very common. I have to rely for my supply at present on the Charity Hospital and any private cases I can pick up. Up to the present, I have not lost a person by yellow fever this year, and only one has died in the Charity Hospital since I received the letter of instructions. That case I captured, and have the proper pathology. The Charity Hospital is fully three miles from my office, near no public thoroughfare, and has to be approached by coaches over a hard road. Three-fourths of the yellow fever cases who die usually select the ungentlemanly and disobliging hour for their departure somewhere between 12 and 4 o'clock A.M. For some reason or other people die slowly when you are waiting for them to do so. They are not at all obliging in that respect. As a matter of fact, few here are devoted to science, and when one begins to look after pathological material, *soon after death*, he will encounter less assistance and sympathy, and more difficulties and obstructions than, perhaps, Dr. Billings imagines.

The sooner after death pathological material is obtained here, the more troublesome and costly. I have succeeded in getting two cases thus far with prospects of another, but yellow fever is not plenty at all outside Military Hospital. I will work on, however. Very respectfully,

D. M. BURGESS, San. Inspector, M. H. S.

The above letter certainly looked discouraging enough, but the old and true saying, "Where there is a will there is a way," was soon exemplified in this case by the receipt of a second letter from Dr. Burgess, dated

HAVANA, CUBA, December 6, 1888.

MY DEAR DOCTOR: *I send you by express, on this date, a box containing pathological material from six undoubted cases of yellow fever.* They are, as you requested, pieces of the liver, kidney, and stomach in each vial. You will see the date of death and time of autopsy and where each person died on each bottle.

This material was most beautifully collected and packed, and I desire, herewith, to express my deep gratitude to both Surgeon-General Hamilton and Dr. Burgess for their great interest and exceptional kindness.

Examination of Pieces of Organs from Six Undoubted Cases of Yellow Fever from Havana, Cuba, 1888.—"No 1. Pedro Marquez, Spaniard, died of yellow fever, at Hospital Mercedes, July 31, 1888, at 4 o'clock, A.M. Autopsy at 7½ o'clock, A.M., the same day."

Histological Examination of Tissues; Liver.—Vessels of the portal circulation engorged, and filled with coagulated blood, with more or less leucocytotic migrations in the vicinity of the capillaries. In some places where the vessels of the portal circulation, the arteries and gall-ducts, are situated, the Glisson's capsule is thickened and replete in connective-tissue cells. This induration appears to have taken its start from the walls of the arteries. There seems to have been a general irritation of the stroma of the organ of a mild character and recent date, extending from the arterial circulation, there being a slight degree of proliferation throughout this tissue. The parenchymatous cells are swollen and contain single nuclei more or less enlarged, while others contain two and some three nuclei, the third being generally smaller than the other two. Still other cells are marked by their excessive swollen bodies, granular appearance, and the entire absence of a nucleus. These cells are sometimes isolated, but more often collected in groups; among them, and scattered through the substance of the organ, is a large number of granulous clusters, varying in individual size and extent, but wanting any sharply defined outline.

Kidneys.—Vessels of medullary portions decidedly engorged, said condition being also present in individual vessels in the cortical substance, some of which are ruptured, with irregularly shaped hemorrhages extending from them into the parenchyma. These extravasations, which vary in size, are dispersed in the immediate subcapsular portion of the cortex. There is a more or less thickening of the walls of the capillaries throughout the cortical portion, but very slight in degree, the same condition being manifest in the membrana propria of the tubes. There is a general diffuse swelling of the epithelial lining of the

[1] Hunting Yellow Fever Germs, *loc cit.*

tubes, with distention of the same, much more marked in some places than in others. The parenchyma filling the distended portions of the tubes presents a diffuse granulous appearance; neither the outlines of the individual cells nor the nuclei being visible. In many places, instead of this diffuse mass, the tubes are loosely filled with desquamated cells, many of which do not present any nucleus, while in others the necleus is of a faded color. In others, again, it is very prominent—granulous colonies are dispersed among these cells. In other tubes the peripheral layer of cells are marked by the distinctly visible nuclei, while the centre of the tube is taken up by a diffuse granulous mass. Scattered throughout the tubes in all portions of the kidney, in transverse and longitudinal sections, may be seen hyaline casts.

[To be continued.]

Hospital Notes.

PHILADELPHIA HOSPITAL.

POST-GLANDULAR MAMMARY ABSCESS.

DR. CLARA MARSHALL drew the attention of the class to two cases of unusual interest. Mrs. W. H., aged thirty-four, married and has seven children, was admitted, May 10, with right breast swollen. On third day after labor she noticed a fissure of the nipple, which was followed by an uneasy feeling in the breast. Castor oil was rubbed on it, but it became worse, and a poultice was applied. On the third day she had a decided chill. After several days no pus appeared; breast was smooth and shiny red; not nodular; general œdema; pitting deeply on pressure; no superficial fluctuation. An ulcerating point appeared at the upper portion of the gland, and an incision was made which liberated ten ounces of pus. The cavity was cleansed with 1–4000 bichloride solution, and dressed antiseptically. The next time it was dressed a counter-opening was made at the dependent part of the gland, and a drainage-tube drawn through the two openings. Iodoform was dusted over the parts and covered with iodoform gauze and cotton. Adhesive straps were firmly applied to support and promote adhesion of the walls of the abscess. At present, May 15, she is doing well, and the swelling and fever have subsided. In their incipiency, the application of ice or hot fomentations to the breast, and the administration of saline cathartics, with quinine, gr. xx, will often prevent the formation of an abscess.

I wish to relate the case of a German woman, aged twenty-seven, who came under my care in 1884, with a post-glandular mammary abscess. Before the delivery of her first child the general symptoms manifested in this last case appeared, and poultices were applied. The breast soon became riddled with a number of openings, which were dressed with the sponge dressing. Morphia was given to allay the pain, and iron and quinine for support. After a perfectly normal labor, a 5¾ pound child was delivered, which died from malnutrition. The breast still continued sore, and the sinuses were freely opened into one; drainage-tube inserted; cleansed with bichloride; dressed with iodoform, and firm pressure maintained; and in about three months from its beginning she thoroughly recovered.

COMPOUND FRACTURE OF SUPERIOR MAXILLARY.

Ransley showed the case of a woman who had sustained a compound fracture of the superior maxillary bone, caused by a kick in the mouth. Wound was dressed antiseptically, but suppuration set in and several sequestra have been removed. Stimulating and astringent washes are used.

The operation for imperforate hymen can be painlessly performed if the parts are thoroughly painted with a 10 per cent. solution of cocaine. In cases where there is much irritability in vaginal examinations, or in local applications to the os uteri, Clara Marshall recommends the introduction of a suppository: ℞.—Olei theobromæ, gr. xv, with cocaine, gr. j, into the vagina fifteen minutes before examination is to be made. It produces both a local and mental sedative effect on the patient.

GENERAL DROPSY.

Dr. J. B. Walker presented the case of a man, who, when admitted on March 7, 1889, had œdema of the lower extremities; lungs waterlogged; pleural sacs filled with an effusion, as well as the abdominal cavity; could not lie down or sit up comfortably. On examination, decided mitral regurgitation was found. The heart's normal activity is to keep the veins empty and the arteries full, but in regurgitation the veins become overdistended, and a consequent effusion of fluid into the serous sacs and dependent parts of the body. This man's whole trouble is referable to his mitral disease. There are three indications for treatment in this man's case: 1, to remove the effusions; 2, to relieve the mitral trouble; and 3, to see to his general health. It is easy to draw off the fluid with an aspirator, but this is contraindicated. It is better to give saline purgatives. This man was given one tablespoonful of Epsom salts, in two tablespoonfuls of water, every morning one-half hour before breakfast. The ascites began to subside, and at the present time most of the fluids have been absorbed and carried off mainly through the kidneys. He will be given the Epsom salts three times a week until all effusion is carried off. Digitalis was given, but as it disagreed with his stomach, one to three grains of caffeine were given ter die for one week, and the digitalis resumed the next, and so given week about. Caffeine is a tonic and not a stimulant, and is an excellent substitute for digitalis in dropsical effusions with heart failure. It answers in many cases where digitalis fails, and is often given in combination with it. As this man was anæmic, he was given the iron lemonade in small doses:

℞.—Tr. ferri chloridi	℥j.
Acidi phosphor. dilut.	℥ij.
Syrupi limonis	℥jss.
Aquæ	℥ij.—M.

The most suitable diet for these cases consists of broiled meats, eggs and milk, and as little water as

possible. To-day (two months after admission) this man is able to sit up and lie down with comfort; his tongue is clean, and the fluids are almost entirely absorbed. The great activity of the kidneys is due to the elimination of the fluids, and not to kidney disease, as one may often be led to believe.

COCAINE FOR IRRITABLE GUMS.

℞.—Cocainæ . . . . . gr. ij.
Aquæ . . . . . ℥j.—M.

This is an excellent remedy, when applied to the gums, when there is much irritability. (*Walker.*)

FOR DYSPEPSIA.

For dyspepsia this prescription is highly recommended:

℞.—Pulvis aromatici . . . . . ʒj.
Creasoti . . . . . ♏v.—M.
Ft. pilulæ No. x. Sig.—Take one pill after each meal.
—*Walker.*

WILL'S EYE HOSPITAL.

ENUCLEATION OF EYEBALL.

IN giving an anæsthetic preparatory to enucleating the eyeball, Keyser precedes it with a hypodermic injection of atropine and morphine. For some peculiar reason it appears anæsthesia is not always borne well during this operation, but by preceding it with the injection mentioned, the risk is very much lessened. Keyser, in many cases, does not give the anæsthetic until he is ready to sever the ball from the nerve, as the local effect of cocaine suffices for the dissection of its muscular attachments. He enucleates without an anæsthetic, whenever he has a patient of sufficient courage, and, as the pain which cocaine cannot relieve is but momentary, occurring when the ciliary nerves are cut, he is inclined altogether to discard an anæsthetic in this operation.

ORTHOPÆDIC HOSPITAL.

TALIPES.

IF upon stretching a tendon pain is elicited, it is an indication that it cannot be straightened without cutting.

In correcting for talipes the foot should not be placed in too straight a position after the operation, lest the divided ends of the tendons be drawn too far apart to secure a rapid and perfect organization of the lymph which is thrown out to perpetuate the continuity of the tendon.—*Goodman.*

SWEET OIL IN POTT'S DISEASE.

A child having Pott's disease of the spine, Goodman directed to be rubbed daily with sweet oil.

Goodman believes that scoliosis, not due to asymmetry or pulmonary affections, arises from the paralysis of certain muscles caused by enervation. Treatment: nutritious diet, massage, electricity and gymnastics.

Goodman's attention to spinal deformity arising from asymmetry of lower extremities was first attracted by an old soldier, during the war, who had noticed it in horses.

London Letter.

ETIOLOGY OF SUMMER DIARRHŒA.

MORE than eight years ago, the Local Government Board resolved to make an inquiry into the conditions determining the very high mortality from diarrhœa in this country. The investigation was entrusted to Dr. E. Ballard, who has presented his inquiries as opportunity offered and has now issued an interim report; this is an extremely bulky document which will require a good deal of study, meanwhile it appears desirable to give here Dr. Ballard's own conclusions. As regards infantile diarrhœa, he confirms the theory, that the temperature of the earth is an all-important point in the etiology; until the mean temperature of the earth at a depth of four feet has attained to about 56° F., the summer rise of diarrhœa is not observed. He, however, also finds evidence that the nature of the soil has a very marked influence; in a town built on a rock with little or no superincumbent material, diarrhœal mortality will be low, while on a soil easily permeable by water and air, diarrhœal mortality will probably be high; the presence of much organic matter in the soil also favors diarrhœa, as do all the ordinary elements of bad sanitation (overcrowding, dirt, want of ventilation, bad water-supply, etc.). Dr. Ballard believes that the essential cause of diarrhœa resides ordinarily in the superficial layers of the earth, where it is intimately associated with the life processes of some microörganism not yet collected, captured, or isolated; that the vital manifestations of such organisms are dependent, among other things, perhaps principally, upon conditions of season, and on the presence of dead organic matter which is its pabulum; that, on occasion, such microörganism is capable of getting abroad from its primary habitat, the earth, and, having become air-borne, obtains opportunity for fastening on non-living organic material, and of using such organic material both as nidus and as pabulum in undergoing various phases of its life's history; that in food, inside of, as well as outside of, the human body, such microörganism finds, especially at certain seasons, nidus and pabulum convenient for its development, multiplication, or evolution; that from food, as also, from the contained organic matter of particular soils, such microörganism can manufacture, by the chemical changes wrought therein through certain of its life processes, a substance which is a virulent chemical poison; and that this chemical substance is in the human body, the material cause of epidemic diarrhœa.

VACCINATION.

The long agitation against compulsory vaccination which has been carried on with all the arts of the unscrupulous agitator for some twenty years or more, has been so far successful that a much harassed government, remembering that Mr. Gladstone, in his eager cadging for votes, professes "to keep his mind open on the question," has promised a Royal Commission to inquire and report as to (1) the effect of vaccination in reducing the prevalence of, and mortality from, smallpox (2) what means, other than

vaccination, can be used for diminishing the prevalence of smallpox, and how far such means could be relied on in place of vaccination; (3) the objections made to vaccination on the ground of injurious effects alleged to result therefrom; (4) whether any means can be found to diminish their ill effects; (5) whether animal vaccination can be further facilitated; and (6) whether the Vaccination Acts ought to be amended. Many people who are periodically revaccinated themselves and have their children vaccinated, believe that the clauses which make vaccination in infancy compulsory must be repealed. They recognize that the step would be retrograde, but the power of unreason is strong; the London New York *Herald* has investigated the matter for itself; a reporter spent the greater part of a day in the inquiry, so that the volume of facts collected was large and well digested. On a seat in St. Paul's Churchyard he entered into conversation with one Jones, who confessed that he had a brother who used to be a most exemplary boy, who did not tear his clothes and went to Sunday-school regularly. In an unfortunate moment he was vaccinated and quickly became a bad boy who tore his clothes and even cut them with his knife, would not go to Sunday school, and altogether became a scandalous example to other boys. This change in his moral nature at first appeared inexplicable, but after a time it was all explained by the discovery that the boy whose arm had yielded the lymph for inoculating young Jones's arm was a bad boy, the son of wicked and dissolute parents.

DR. BARRY'S REPORT ON VACCINATION AND SMALLPOX IN SHEFFIELD.

The epidemic of smallpox in Sheffield last year has been carefully studied by Dr. Barry, for the Local Government Board, and his report has not afforded the antivaccinationists much satisfaction. He made a home visitation and found that there were about 70,000 children under ten years of age; the number of children attacked among the vaccinated majority was 0.5 per cent., while among the unvaccinated minority 10.1 per cent. were attacked; the death-rate of the vaccinated children was 0.09, of the unvaccinated, 44.0; so that a vaccinated child is about five hundred times less likely to die of smallpox than an unvaccinated child. Sheffield was a well vaccinated town; if, like Leicester, vaccination had not been enforced the evidence goes to show that where there were in reality 9 deaths there would have been 4400. Yet the most favorite argument of the antivaccinationists is that the medical profession only defend the vacccination laws because they put fees into their pockets!

A NEW DISINFECTANT.

Dr. Klein has reported on the germicidal properties of iodate of calcium which has been manufactured by Mr. Weaver, C. E., as a disinfectant. It has very feeble powers as compared with perchloride of mercury, but it does possess very distinctly the property of checking the growth of the anthrax bacilli; in this respect it is superior to carbolic acid and permanganate of potash, and it has the great advantage of being harmless to the human system. Doses of one and two grains, given to adults "several times daily and for several successive days," produced no physiological effects, except that presence of iodide was demonstrable in the saliva. It is possible, therefore, that iodate of calcium may have a future in therapeutics, as a disinfectant at least.

MILK SCARLATINA.

The report of the medical officer to the Local Government Board has been issued since my last letter. It is chiefly remarkable for the fresh pathological evidence advanced by Dr. Klein tending to prove the theory that there is a epizoötic disease of cows, characterized by sores on the udders, which is the same disease as human scarlatina. His new inoculation experiments were performed on healthy milch cows four or more weeks after calving; he used cultures of his *streptococcus scarlatinæ*; in four experiments the series of cultures were started from the blood or pericardial fluids of calves which had been experimentally infected with the human *streptococcus scarlatinæ*; in two the cultures had been made direct from the human being suffering scarlatina. After from four to nine days sores appeared upon the teats, then a more general erythematous affection of the skin, with loss of hair and scurfiness was observed, and there was more or less general disturbance characterized by fever and sometimes by pulmonary symptoms. The morbid changes found in animals killed at this stage are widespread, but not very distinctive. Dr. Klein, however, considers that they essentially resemble those observed in human beings dying of scarlatina. A great part of the report is occupied by meeting the criticisms of Prof. Crookshank, who, it may be remembered, started the theory that this disease in cows was in reality cowpox, and that the *streptococcus scarlatinæ* was one of the organisms of suppuration which might be found indifferently in a suppurating cowpox, or a suppurating scarlatinal throat.

THE VARIETIES OF STREPTOCOCCI.

Dr. Klein has a very elaborate paper on the second point. Dr. Buchanan, the principal medical officer, has a graphic simile in his introductory comments. "To the less educated judgment" he writes: "there is as little difference between one and another chain-forming micrococcus as, to the eye of the ordinary dweller in towns, exists between the swift, the swallow, and the martin." Dr. Klein has set himself to discover characteristics in the cultivations which will enable the bacteriologist to distinguish between streptococci morphologically so similar as to appear identical. The criteria are very minute points, and without repeating his experiments no one could give any opinion on their validity.

SYMPTOMS OF COW SCARLATINA.

It may not be out of place to notice the symptoms observed in cows believed to be guilty of transmitting scarlatina to human beings. The first sign is a sore or sores on the teats; these are at first small, not more than one-eighth to one-quarter inch in diameter, more or less circular, and look like superficial abrasions of the cuticle; after a short time they become

covered with brown scales, but always remain very superficial; fever and constitutional disturbance are often slight and may be easily overlooked, the cow remaining in good condition and yielding plenty of milk, but in other cases the animal goes out of condition rapidly; sores on other parts of the body besides the teats are not uncommon, and loss of hair in patches is frequent; the milker's hands are seldom or never rendered sore by handling the teats, which is in marked contradiction with the behavior of cowpox and some forms of "spurious cowpox."

TOTAL EXTIRPATION OF THE LARYNX.

Mr. Charters Symonds, of Guy's Hospital, has had a successful case of total extirpation of the larynx for epithelioma. The patient was a man aged forty-one, under the care of Dr. Greville Macdonald; when he first came under observation in April, 1888, Dr. Macdonald removed the growth with forceps, as an external operation was objected to; it quickly recurred and after some further hesitation the patient finally consented, and on October 28, Dr. Symonds performed a partial operation; the growth quickly recurred and seven weeks later the whole larynx was extirpated; he made a fairly rapid recovery, and when shown to the Clinical Society on April 26, he was in good health and spirits, and there was no sign of recurrence after four months. He could speak in a low, distinct, though gruff voice, and this was managed by passing through the upper wall of the canula a curved tube which ran up to the base of the epiglottis, and admitted the air when he closed the canula with the finger. This was found much simpler than the artificial larynx, and, moreover, the patient preferred the sound of his own voice. The vibrating structure appeared to be the mucous membrane of the pharynx running back from the epiglottis. This is said to be the first recorded case in which the patient was able to speak after total extirpation of the larynx; the voice was gruff and loud, but speech was intelligible; the Vienna reed artificial larynx has a tone like a toy trumpet.

SULPHONAL AND HYOCINE.

One hears sulphonal well spoken of as a hypnotic and sedative in very various quarters. It seems to be specially of use in the treatment of various forms of mental disorder where there is much excitement, but it is also becoming popular with "fashionable physicians." At present we are told that no ill effects follow its use, but this is a stage through which apparently every hypnotic goes; it is a derivative from the alcohol series, and it is, therefore, not unlikely that by this time next year some physician will write a paper describing the dire results of sulphonal addiction, for it is now being somewhat recklessly prescribed for insomnia. In asylum practice it is not likely to replace hyoscine, which as a cerebral sedative is so safe, certain, and rapid that it is earning the slang name of "therapeutic restraint." It is best administered hypodermically, the dose being $\frac{1}{100}$ gr.; if this fails $\frac{1}{100}$ gr. may be given in a few hours. It is only in extreme cases that doses of $\frac{1}{80}$ or $\frac{1}{60}$ gr. will be required.

A COUGH TINCTURE.

The following prescription for a palatable and fairly effectual cough mixture may be new to some of your readers; it goes, I am told, by the name of Gee's tincture, and is very popular. It has the merit of not taxing the prescriber's memory very severely.

℞.—Syrupi tolutani,
Oxymel scillæ,
Tr. Camph. Co . . . . . āā ℥j.
M. ft. Tinct.
Sig.—One teaspoonful occasionally when the cough is troublesome.

EAST LONDON POVERTY.

Mr. Charles Booth—who has nothing to do with "General" Booth of the Salvation Army—has written a simple book on the poverty of East London, giving interesting statistics as to the incidence of poverty in that district; poverty is, of course, a relative term, but the sense in which it is generally understood in this country, Mr. Booth's evidence is that there is very much less than is usually supposed. Experience shows that a sober laborer who earns from 21 to 23 shillings a week can live and support a wife and two or three children in comfort, as comfort is understood by town livers. Workmen who know both countries state that this wage is about equivalent to $15 or $16 dollars a week in a city in the States. The wages of the vast majority of East Londoners are, however, according to Mr. Booth, above this:

The same work gives the foreign born population of East London (and Hackney) as 27,514; this is 3.25 per cent. of the total population. There are 7583 Germans, 5964 Poles, 2870 Dutch, 1332 Russians, and 686 born in the United States. The Jews number 15,000.

THE ROYAL SOCIETY.

There were a large number of candidates for the Fellowship of the Royal Society this year, including a fair proportion of members of the medical profession. For many years there has been an indisposition to recognize clinical eminence. This year there has been no exception. Among the successful candidates there is no practising physician or surgeon. Dr. E. Ballard is one of the medical inspectors of the Local Government Board, who has attained considerable eminence as a sanitarian and statistician; reference is elsewhere made to his most recent work, a Report on Diarrhœa. Dr. D. D. Cunningham is the Professor of Pathology at Calcutta, whose name is best known in association with that of the late Dr. Timothy Lewis. Prof. Gerald Yeo occupies the Chair of Surgery at Kings College.

Dr. Clifford Allbutt, who has been for a good many years the leading consulting physician in Leeds, and one of the most prominent members of the profession in the north of England, has been appointed a Commissioner in Lunacy. As the office is poorly paid, and the work very onerous and trying, his acceptance of the office has caused great surprise.

The Emperor of Germany has conferred "the Red Eagle Third Class" on Dr. Felix Semon, the laryngologist, of St. Thomas' Hospital.

VOLTAIC ELECTRICITY IN THE TREATMENT OF CANCER.

MORE than ordinary interest attaches to the report made by Inglis-Parsons[1] upon the treatment of cancer by voltaism. The failure of every method of treatment enhances the desire to find a remedy for this opprobrium of our art. The only method which has won the confidence of the profession is early and thorough extirpation, a principle to whose establishment the younger Gross contributed the best work of his life. But even the earliest and most comprehensive cutting is not successful in nearly all cases, and it leaves out that greater number in whom the disease has been suffered to pass the favorable period for lasting success.

Dr. Inglis-Parsons' views as to the action of galvanism are summed up in the following proposition: That while the normal tissues of the body have the power of recuperating from any effect produced on them by the transport of elements, the cells of tumors being of lower vitality might be checked in their growth and, perhaps, in time destroyed. He details experiments going to show that the constant current exerts no decomposition in the interpolar region, but when the current is suddenly interrupted marked signs of disturbance follow, which he attributes to some destruction of tissue. If this be true, he believes that the correct method of curing cancer is found. The impact of a powerful current suddenly flashed through, causes such injury of the tumor cells in or near its path as leads to their gradual atrophy. In treating fibroids the danger of gangrene leads to the avoidance of interruptions of the current, but in cancer the lack of an investment, and the free supply of nutrient vessels render this precaution unnecessary.

The *modus operandi* is as follows; "The patient is anæsthetized; the current is then passed through the tumor and all the tissues for some inches round it by means of fine, insulated needles, so as not to injure the skin. A battery of 70 cells with an electro-motive force of 105 volts is used; the intensity of the current to commence with is 10 milliampères, gradually increased to 600 milliampères, and flashed through the growth in every direction from fifty to one hundred times according to circumstances. The pulse and respiration were carefully watched. One out of the four cases treated, a woman, aged sixty-three, with extensive carcinoma of the left breast, a presystolic *bruit*, and weak, intermittent pulse, was unable to stand more than 250 milliampères, for this reason: when the current is applied to the left breast electrical stimulation of the heart occurs, and if this organ is healthy an increase in the strength of its contraction appears to take place after its passage; but with the patient who had cardiac disease, the improvement only continued up to a certain point, and then the intermittency increased and great irregularity occurred."

When the current was passed through a secondary growth in the axilla of the same patient it could be increased to 600 milliampères with safety.

The effects consist in cessation of growth, alleviation of pain, shrinking and hardening of the tumor, and improved health. The growth becomes inert; probably reduced to fibrous tissue.

The advantages of this method of treatment are: There is no destruction of the normal tissues of the body, and if recurrence should happen it may be stopped by a repetition of the treatment. So far, cases able to bear the current at the full strength required have had no recurrence. Patients are not obliged to lie up, but can go about the day following the application. The current can be used in parts beyond the reach of the surgeon's knife.

Of the cases recorded, the first was one of carcinoma of the left breast and axilla. Two operations were made upon the breast and one on the axillary gland. Six months later the patient reported good health, no pain, the tumors smaller and harder.

The second was a similar case, but far advanced. The current could only be used up to 300 milliampères, on account of the heart, and the results were not so satisfactory, though great improvement ensued.

The third case was of uterine cancer, pronounced beyond operation.

The results of the voltaic treatment, as described three months after the application, are as follows: Hemorrhage ceased, vesical irritation gone, can do some work, much less pain in groin, uterus released from adhesions and freely movable, no infiltration surrounding, remains of growth very hard, does not bleed when touched.

The fourth case of mammary cancer had a history like the first, and after the lapse of three months the arrest of growth still endured.

Even in this meagre record may be seen evidences that the method is full of promise. The cases are few, and the time elapsed since the operation is short; but we are not rich in agents which will check a rapidly growing cancer and reduce it to quiescence

[1] *British Med. Journal*, April 13–27, 1889.

for three months. Even should these cases prove exceptional, and wider experience minimize the power of the current as an arrester of growth, its value as an analgesic in these cases will probably remain, being in harmony with the well-established virtue of galvanism in relieving other pains; notably that of neuralgia.

The further experience of Dr. Inglis-Parsons will be looked for with interest.

Annotations.

HUMAN AND BOVINE TUBERCULOSIS.

BRUSH (New York Academy of Medicine) has made a study of the relations of human and bovine tuberculosis. In considering the effects of climate, he finds the only constant associated factor in the prevalence of human tuberculosis is the prevalence of the disease among their domestic cattle. In Africa, tribes which have no cattle, on account of the tsetsè, are not affected with tubercle; while coast tribes, which use milk and drink bullocks' blood, die of phthisis. In Denmark there is more than one cow to each two inhabitants; and the death-rate from phthisis is between two and three per thousand. In Iceland there is one cow to four inhabitants, and dairy products are usually sold; while phthisis is very rare. In the Azores, phthisis is very rare, the people using goats' or asses' milk. The Esquimaux tribes have no phthisis, except those who keep cows. Australia had none, until cattle were introduced, in 1826. Madagascar has great herds of cattle, and the natives live on milk, meat, and rice, and largely die of phthisis. In Algiers, Greece, India, the Russian Steppes, parts of Italy, Egypt, and Ecuador, the use of the cow and the prevalence of phthisis coincide exactly.

Dr. Brush detailed an experiment which can easily be repeated. He fed the lungs of a cow dead with tuberculosis to his chickens, and soon one hen showed symptoms of laryngeal phthisis, verified by post mortem. Twenty-three of her eggs were put under another hen; all developed chicks, but all were dead when the shells were broken. In the discussion which followed, the speakers agreed generally as to the agency of tuberculous milk and meat in transmitting the malady to man, but did not consider this the only or the most important source.

FEMALE INEBRIATES.

IN Mrs. L'Oste's little paper upon the treatment of female inebriety in the cultured classes (London, H. K. Lewis) are given some valuable deductions from her twenty-seven years' experience. She speaks of the life of children who inherit a taste for drinks and condiments. The nervous debility resulting from obstetric disorders comes in as a fertile cause, but we believe that for this may too often be substituted the giving of alcoholic drinks to nursing women. Indeed, Mrs. L'Oste mentions several cases as due to the use of eau des Carmes de Melisse—a pleasantly flavored spirit used as a pick-me-up.

She strongly advocates a city home for the treatment of ladies, who require more diversion than that afforded by nature. She finds women quite as amenable to treatment as men.

THE BLIND DEAF-MUTE.

LAURA BRIDGMAN, the famous blind deaf-mute died on May 24, in her sixtieth year. The teaching and mental development of this girl have gone into history as a wonderful example of what can be done by patient pedagogic skill. Beginning by teaching her the letters and spelling the names of simple objects, Dr. Howe proceeded to other words as her capacity increased, until she eventually became an intelligent, educated woman. No knight-errant ever released a highborn lady from so impenetrable a prison.

A LARGE FAMILY.

THE Arkansas *Gazette* has been making a search for the largest family in that State, and has found it. Mr. and Mrs. W. D. Green, of Pike County, have had twenty-three children, eighteen of whom are now living. This remarkable couple produced their first child in 1836, when the father was twenty-three and the mother eighteen years old. The twenty-third child was born in 1886; forty-four years later, when the father had reached the age of sixty-seven and the mother sixty-two years. All the births were single. The facts are attested by affidavits. The couple have had eighty-four grandchildren and fifteen great-grandchildren. The progenitor of this great family is a blacksmith. Can any of our readers produce a family record to equal this one? Shall we imitate our Arkansas contemporary and offer a silver mug to the couple reporting the largest family of children?

Society Notes.

AMERICAN SURGICAL ASSOCIATION.

THE American Surgical Association held its annual meeting at Washingson on the 14th, 15th, and 16th of this month. The meetings were held in the new Army Medical Museum at the corner of seventh and B streets. The meeting was not only well attended by the members of the Association, but it attracted members of the profession from far and near in large numbers to listen to the debates. There were certainly twice as many visitors present as there were members.

On Tuesday morning the session was opened by the very interesting address of the President, DR. DAVID W. CHEEVER, of Boston.

He was followed by DR. M. H. RICHARDSON, of Boston, one of the surgeons to the Massachusetts General Hospital, with an able paper on The Surgical Treatment of Gangrenous Hernia. This was discussed with much interest by the members, Dr. Moore, of Rochester, taking a prominent part in the discussion.

The second paper, on The Early Diagnosis of Morbid Growths, by DR. J. COLLINS WARREN, of

Boston, Professor of Surgery in Harvard University. Drs. F. S. Dennis, of New York; P. S. Connor, of Cincinnati, and B. F. Watson, of Jersey City, had been appointed to open the discussion.

A paper on Hernia; a Comparison of the Various Methods Adopted for its Radical Cure, inviting discussion of their respective merits, was read by Dr. C. H. Mastin, of Mobile. The appointees to open the discussion were Dr. George W. Gay, of Boston; Dr. T. G. Richardson, of New Orleans; and Dr. M. H. Richardson, of Boston.

A paper was then read by the President of the Association, Dr. David W. Cheever, of Boston, Professor of Surgery in Harvard University, on Sarcoma of Tonsil; excision, with specimens removed; prognosis, history of case; description of operation, with full charts as to feeding and as to closing of the pharynx; exhibition of photographs and of tumors removed. The paper was discussed by Prof. D. Hayes Agnew, of Philadelphia; Dr. J. Collins Warren, of Boston; and Dr. A. Vanderveer, of Albany.

The next paper, on Wednesday morning, was one on Free Division of the Capsule of the Kidney for the Relief of Nephralgia, by Dr. L. McLane Tiffany, of Baltimore, Professor of Surgery in the University of Maryland.

But few of the members had any experience in operations on the kidney for this purpose, though several cases were quoted where the kidney had been opened for exploration only, and no disease found, and where the pain ceased after the operation.

Dr. Homans, of Boston; Dr. Yandell, of Louisville; and Dr. Keen, of Philadelphia, took part in the discussion, the latter relating a case where the grating of stone was distinctly felt with a needle introduced into a malignantly diseased kidney, and where on postmortem examination no stone was found, and it was considered that the sensation must have been due to a degenerated vessel on a small transient calcareous deposit.

Dr. Tiffany was followed by Dr. J. M. Barton, of Philadelphia, Surgeon to the Jefferson College Hospital, in a paper on Digital Divulsion of the Pylorus, with a report of a successful case and a study of the diagnosis and best methods of operation from a collection of twenty-five reported cases.

Dr. Bull, of New York, who has had the only other successful American case, and who had been appointed to open the discussion, was unfortunately unable to be present.

Dr. Kinloch, of Charleston, S. C., opened the discussion, and expressed his doubts about the permanency of the cure, and was followed by Dr. Richardson, of Boston, who had noticed how tolerant the stomach was of surgical interference and how soon the wounds of the stomach were perfectly closed. He, however, preferred the interrupted Lembert suture for this purpose, but had been obliged to make a much larger abdominal wound when operating on the cardiac orifice.

Dr. Homans, of Boston, endorsed this statement about the tolerance of the stomach, and related a case of an insane woman in whose stomach a ball of hair had formed from the repeated swallowing of a small number of hairs. In this case a seven-inch incision in the stomach was necessary to deliver the mass. This wound healed by first intention, with recovery of the patient.

Dr. Barton, in closing, stated that he still had some doubts about the permanancy of the cure, and considered this question as not yet fully settled, though the evidence that he had quoted he considered thoroughly reliable and fully justified the operation. In reply to Dr. Richardson's remark that in operating on the cardiac orifice he had been obliged to use a much larger abdominal incision, Dr. Barton stated that in his experience when the cardiac orifice was obstructed he had found the stomach contracted and gathered into a small mass, lying deeply in contact with the spine, and the whole hand would certainly have to be introduced in order to find and to bring the stomach into view; whereas in the pyloric obstruction the stomach was always enormously dilated and laid in contact with the front wall of the abdomen.

A paper was then read by Dr. Theo. H. McGraw, of Detroit, Professor of Surgery in the Detroit Medical College, on a Contribution to the History of Gunshot Wounds of the Intestines. He stated that soft tissues do not deflect balls in the abdominal cavity, and their apparent erratic course was due to movement on the part of the patient at the moment of the injury and to the subsequent shifting of the moveable viscera. He considers that an incision made in the course of a ball will give the nearest access to the injured parts, and that tissues that cannot be brought to such an incision could not have been injured. When an injury is more than four hours old there is great danger of rupturing protecting adhesions. The danger of the abdominal section is strictly in proportion to the length of time that the abdomen is open.

He further stated that the incision, if possible, should be made over the wound of entrance; that the examination should be limited to the viscera near the wound; that wounds in the intestines need not be sutured, if they do not leak they will be closed by inflammatory deposits. Treat the large wounds first, and if the patient sinks during the operation, the smaller ones may then be left to nature if the patient rallies: never eviscerate a patient.

Dr. Yandell was not able to fully agree with the statement that balls do not deflect after entering the abdominal cavity; he cited some cases in which they did deflect. He agreed that evisceration should not be performed, but insisted that each and every part of the intestine should be passed through the fingers and examined.

Dr. C. B. Nancrede, always prefers the median incision; he would also object to eviscerating the patient, but insists on thorough examination of every part of the intestine; death has been caused by one wound being overlooked. He treats the first wound he finds first, be it large or small; there may be difficulty in finding it again if not treated at once; treat all wounds; mere contusions will often slough and produce fatal peritonitis. He called attention to the

great shock produced when we approach the solar plexus.

Dr. Mears related the cases of Dr. Packard's, where one pistol ball produced twelve wounds of the intestines. He prefers the median incision; it can always be lengthened at any time; lateral incisions cannot. He thinks patients would do better without operation than with an incomplete operation.

Dr. Kinloch, of South Carolina, thinks there were two false doctrines in the paper. 1. Leaving one wound and treating another. 2. That wounds of intestines will heal without suturing.

Dr. Mastin, of Mobile, related a case where a thirty-eight calibre ball entered one inch to the right of the umbilicus and slightly below, entered the bladder and was found in the prostate; it had produced nine wounds of the bowel in its passage.

Dr. Dennis, of New York, advocated the median incision without exception; wounds of the iliac vessels cannot be controlled by any lateral incision; if free bleeding is occurring, the median incision can be made in half a minute, if the blood wells up so fast that it obscures its source, compress the abdominal aorta above and the femoral veins below and temporarily check it. In treating gunshot wounds of the abdominal cavity treat hemorrhage first, and, then close the wounds of the bowel in the order they are found.

Dr. Weeks recalled Senn's method of finding wounds in the intestines after the abdomen is opened by the use of hydrogen gas. When there is no more leakage and the bowels remain distended there is no unclosed wound.

Dr. Weeks, of Portland (a candidate) read a paper on drainage, and related some experiments in which he had used antisepticised animal bloodvessels with success on both animals and the human subject; the drains so prepared were absorbed in seven days.

The Society then proceeded to election; they chose Dr. Yandell, of Kentucky, for President; they added Dr. Nancrede, of Pennsylvania, to the list of Vice-Presidents, and elected the following new members: Dr. Weeks, of Portland, Me., Professor of Surgery in the Medical School of Maine; Dr. Weir, of New York; Dr. John Homans, of Boston, Surgeon to the Massachusetts General Hospital; Dr. Lewis A. Stinson, Professor of Surgery in the University of the City of New York; Dr. Fred. Lange, of New York; Dr. Lewis A. Pelcher, of Brooklyn; Dr. L. C. Lane, Professor of Surgery in the Cooper Medical College of San Francisco, and Dr. Arthur J. Cabot, of Boston.

Letters to the Editor.

A CASE OF WHOOPING-COUGH TREATED BY SULPHUR FUMIGATION.

"ONE swallow does not make a summer;" neither does one cure prove the remedy to be a specific. Yet as the advent of the first swallow is hailed as the harbinger of the summer season, so may we regard the decided effects of a remedy, whether real or apparent, whether in a succession of cases or for the first time, as a sufficient incentive publicly to call attention to it. The "bacillus tussis convulsivæ," as described and named by *Affenanieff*, is now regarded as the specific cause of whooping-cough. It is also known to the profession that sulphurous-acid gas has been recently used, by inhalation and fumigation, in the trearment of this disease. The successful application of this remedy in a case recently under my observation, occasions the following statement:

Viola J., æt. four months (born January 28, 1889), commenced coughing when twelve weeks old, which at first was regarded as caused by an ordinary bronchial catarrh. Ten days later, however, the unmistakable symptoms of whooping-cough were manifest, and the baby was placed under the usual treatment during another ten days, with the usual result, viz., an aggravation of symptoms. Indeed, the prognosis was at this time quite serious. It must be stated here that the source of contagion is positively known. The mother claims to be able to "identify the kiss which done it," to use her own language, and the children of the family are still "barking" and have been the known source of infection in various other directions.

The administration of medicine by the mouth being well nigh impossible on account of the frequently recurring paroxysms and the attendant vomiting, the treatment by inhalation of sulphurous-acid gas suggested itself, which was rendered the more feasible because the family occupied a house with only four small rooms. The treatment commenced on May 6, and ended on May 18. The parents were directed to use their own bedroom, unfold and hang up as much as was possible in the small room, their own as well as the child's bedding and clothing, close the door and windows, generate the sulphurous gas, and remain in it together with the child as long as was possible, taking the precaution of opening the window or door in case the fumes should become suffocating. These directions, however, were not implicitly obeyed during the first week on account of fear of "choking the baby to death;" the kitchen, with open door and window, being used, and the clothing not being fumigated. Yet the amendment was manifest from the beginning, the paroxysms recurring less and less frequently, and becoming shorter and shorter in duration. But during the second week, when they found that "the baby could stand it better than us," the treatment was faithfully attended to (on May 12, 14, 16, and 18), when every vestige of the cough and other symptoms had entirely disappeared. From that date to this (May 25) there has appeared no untoward symptom whatever, and the child is hale and hearty.

The method of producing the gas was simply this: An iron pan was placed upon the floor on a brick, in which was heaped a small handful of roll sulphur broken into small pieces, among which was placed a lump of camphor the size of a filbert, which, being set on fire, produced an abundance of fumes.

613 N. Sixteenth Street.

DOSIMETERY.

LAST year, I wrote a brief article upon the Dosimeteric Method of Treating Disease, which was published in the *Medical Summary* of Philadelphia. Since then I have been communicated with by many in the profession in regard to where literature on the subject could be procured; to which inquiries I returned the desired information.

I will now give your readers briefly my further observations and reflections on the merits of the dosimetric method, claiming that observation and reflection constitute the sum of all knowledge.

If therapeutics were an exact science, and physicians were perfect diagnosticians, dosimetery, to my mind, would be of little importance to the average practitioner.

But how stands the case?

I read, the other day, that a certain person, cynical as to the merits of the medical profession, called upon some five to ten of the learned Esculapiuses of the city of New York for medical advice, and that no two of them agreed regarding the management and medication, or even the disease itself. Such being the case, is it to be wondered at that trustworthy men seek something more exact, more in keeping with the evolution of science and of art?

Dosimetery deviates from the beaten tract of expectancy in the management and the therapeutics of disease, using small, but repeated doses of alkaloids and extracts until the disease is "jugulated" or aborted, not awating its fastening upon the system, and closing the avenues of escape, either through the skin, stomach, lungs, or bowels.

Dosimetricians at once, by the use of proper alkaloids, stimulate the vaso-motor nerves, open up the natural avenues, and thus hasten the escape of malaria or contagion before either has found and arranged its nidus; from which it starts out poisoning and destroying nature's only means of throwing off the intruder, whose first effect is irritation, then inflammation, rapidly passing into mortification, and death.

Let me ask one question concerning typhoid fever, is active treatment necessary? You will smile, perhaps, but the question is intended seriously. Thus say those who believe in expectancy: "Typhoid fever is a cyclic malady; it must be permitted to run its course, we must confine ourselves to a condition of armed expectation, combating the complications which arise, and which accompany the disease to its natural conclusion."

This is, indeed, a remarkable plan for the supposed master of the healing art to adopt. We reach the natural term of disease, provided that the patient does not come to a full stop on the way, killed by organic lesions, which the physician had allowed to occur. The doctor combats with these lesions "after they have become fully established," that is, if he recognize them; but they then are too powerful for medical aid.

Do we not often observe that these cyclic maladies leave their customary course, and conduct their victims from life to death by the shortest course, passing through the regular stages of congestion, inflammation, and finally, dissolution?

"How shall we," says the dosimetric physician, "contract this circle?" We must rescue the patient by taking him through the weak point in the circle of the disease which encloses him. Typhoid fever presents just such weak points. There is about the fifteenth day, the period in which the morbidly elevated temperature of the body in fever is declining towards the natural standard, a defervescence, frequently mentioned by medical writers. This cannot have escaped the observation of any physician of large experience, who should promptly have taken advantage of it, and saved his patient by the timely support of the vasomotor nerves, thus preventing that sometimes fatal prostration, so likely to follow neglect at that particular crisis of the disease.

"Fever is the enemy we have to fight," says Prof. A. Burggram, and physicians are beginning to agree upon this extremely important matter; for we observe that everywhere the active male or female in the prime of life, often has a very close call, and often sinks into a premature grave, for want of the proper and timely administration of medicine.

It is true that a certain class of physicians gravely count the pulse and take the temperature, though it is hard to give the reason, therefore, since the occupation cannot be valuable, except as a sort of study in natural history. Others, in combatting the fever, have done it more like Titans than physicians, attempting to break the temperature, as it were, by throwing boulders at it. They have given baths of iced-water, phenic acid internally and externally, and sulphate of quinine in quantities of half a drachm to a drachm daily.

"Above all things, let us," says Prof. Burggram, "combat fever always and everywhere, for there is no possible fever which can be salutary, but let us not crush out our patient's life by our treatment." This article is now too extended; yet I will state that the world of medicine may be said to exist in two great divisions. In the one traditional medicine, resting upon antique routine treatment, and believing itself strong on account of its immense arsenal of drugs, which are distributed with an over-generous hand. In the other category are physicians, who firm in their convictions and opposed to routine treatment, attack the malady vigorously and with confidence, while striking simultaneously at both causes and symptoms.

To minds which seek the truth and aim at definite and satisfactory results, dosimetry opens certain new and effective methods or lines of treatment. In all maladies the dosimetric physician keeps in mind two fundamental principles: First, to combat the cause while sustaining the vitality; second, to combat the symptoms, each one separately if there be need, with arms whose force is exactly measured, and which act with certainty.

Prof. Burggram, in all his writings, has been especially careful to keep in mind, that dosimetry is not to be regarded as a new "system" of medicine, but a new "method," and a method of the most accurate therapeutics. And as such uncertain action of medicines exist in proportion to the complexity of the

combinations, he has confirmed his therapy almost entirely to extracts and alkaloids.

J. M. Hole, M.D.

Salem, O.

FLEXIONS AND VERSIONS OF THE UTERUS.

NORMALLY, the uterine canal is not straight, but curved, constituting a normal or physiological anteflexion. In considering the possibility of uterine displacement, it should be borne in mind that the fundus, at the uterus, is not firmly fixed by any of its attachments, but especially in an antero-posterior direction may vary its position quite considerably. In fact, the condition of the bladder or the rectum as to emptiness or repletion will make quite extensive changes in the position of the fundus uteri. If the fundus drops forward, carrying the os and cervix backward, the result is anteversion; if the proceeding be reversed, the result is retroversion. As a matter of fact, neither flexions nor versions usually occur alone, anteversion being usually accompanied by an increased degree of anteflexion and retroversion by a degree of retroflexion. The extreme point of version may be said to consist in a complete inversion of the axis of the organ; thus in anteversion the fundus would lay low and directly behind the symphysis pubis, while the os would be found low down in the hollow of the sacrum. In a state of complete emptiness of the bladder, the uterus falls still farther forward and becomes temporarily anteverted. Great distension of the bladder produces a retroversion. From either of which conditions the organ usually assumes its normal condition upon removal of the cause. If, however, a laxity of the ligaments supporting the uterus, such as may be induced by rapid or recent child bearing, be present, or if from chronic inflammation, or the presence of fibroids, or from any other cause, the fundus be preternaturally enlarged or heavy, there is a tendency for the malposition to become permanent; if this be further assisted by sudden violent exertions, such as lifting, straining at stool, falls or leaps from a height. Add to the causes producing version, a weakening of the cervical portion of the uterus from any cause, and flexion may result instead of version; and the flattening of the bloodvessels at the point of flexion, the congestion of the fundus and consequent enlargement produced tends to make the condition constant. Indeed, I believe that most cases of uterine enlargement, congestion, and chronic inflammation are traceable to flexions as a cause: a position, however, not in harmony with all gynecologists. There is no fixed standard whereby the uterus may be judged in regard to the normal position of the uterus. Every woman is a law unto herself. The uterus has a range of normal positions, and this range will vary in each woman according to the symmetery of her pelvis and the length of the ligaments, which nature has supplied to the organ.

Barker, Ark.

A case of torticollis is reported as due to a stroke of lightning.

The Inquirer.

THORACIC ABSCESS.

THE case of thoracic abscess, described upon page 66 of The Times and Register, looks like an empyema. Let us see if this explanation will fit the description given by Dr. Milner. It began with a fever—that is, acutely; followed by pointing, prolonged suppuration, resisting all efforts at healing until finally another opening was made into the lung, and then the chlorinated soda solution did good. The mental hebetude was due to septic poisoning. So far, the explanation is satisfactory; but it does not account for the pyuria or for the intestinal hemorrhages. Is it possible that the reporter has mistaken a free deposit of urates for muco-pus? It sometimes happens, at the crisis of a fever, that the urine is loaded with deposits which resemble pus, but do not prove to be so on microscopical examination. The hemorrhages do not appear to have any possible connection with the other symptoms. They may have been due to duodenal ulcer, from embolism, or to hemorrhoids; but the history is incomplete.

Could this have been a hepatic abscess? This might have existed in a latent condition, and the fever have been due to its invading the pleura. The opening, however, was not where we would expect from a hepatic abscess, and the pus is not described as bloody. The history does not show Dr. Milner's reason for persistently administering alteratives, when the indication appears to be plainly for iron, quinine, and rich diet. Quinine, in large doses, is assuredly the remedy in case of profuse suppuration, with fever and prostration. M. L. W.

Jamestown, Dak.

G. W. C.'S CASE.

IF Geo. W. C.'s case is one of diabetes, as seems probable from the symptoms, it is somewhat singular, as being apparently due to an injury. If it is quite certain that the appearance of the symptoms followed immediately upon her fall, the case should be recorded. There is no reason why glycosuria should not follow an injury of this sort, as well as one made by the experimenter.

In one case treated by the writer syzygium jambolanum has produced a decided change for the better. It was given in doses of a teaspoonful thrice daily; increased to six times afterwards. J. A. W.

Duluth, Minn.

Has "Geo. W. C." examined his patient's urine for sugar? Jno. A. R.

It may be that the phonograph will prove of value to the demonstrator of physical diagnosis. By its use, a typical crepitant râle, a pleuritic friction sound, or an aneurismal bruit may be preserved and reproduced for the edification of successive classes of students. This will enable the teachers in cross-road colleges to become quite independent of the clinics for their material.

Book Reviews.

THE BACTERIA IN ASIATIC CHOLERA. By E. KLEIN, M.D., F.R.S. London and New York: Macmillan & Co., 1889.

Dr. Klein is the most prominent of the few who still refuse to accept Koch's comma bacillus as the true cause of cholera, though acknowledging its diagnostic value. With him the verdict returned is the Scotch one, of not proven. Dr. Klein is an able worker, of acknowledged skill, and his reasons for his faith are clearly stated in this volume, which can be obtained at Lippincott's.

A LABORATORY GUIDE IN CHEMICAL ANALYSIS. By DAVID O'BRINE, E.M., M.D., D.Sc. Second Edition. New York: John Wiley & Sons, 15 Astor Place. 1889.

A practical guide in chemistry, adapted to the wants of the student. The book has been prepared with care, and the author tells us that he has verified the tests given. This is not a superfluous bit of information. The late Dr. Jerome Kidder, while in the Navy, prepared a little manual for the use of navy surgeons. In framing this, he found a difficulty with the nitrate of urea test, which he found had been copied from book to book, and the error was traced back to Sutton, who had made it originally.

A MANUAL OF INSTRUCTION IN THE PRINCIPLES OF PROMPT AID TO THE INJURED. By ALVAH H. DOTY, M.D. New York: D. Appleton & Co., 1889.

This manual covers the points which should be taught to the ambulance corps of a military organization, and seeks to give such instruction in the management of emergencies as a non-medical person can comprehend and utilize. The anatomical introduction is judiciously worded; it is clear, and does not cover too much for those to whom the book is to go. The eighty-nine plates are praiseworthy, except the colored diagram of the arteries, which careless press work has spoiled in the copy before us. Altogether, in general utility the book is far ahead of any work on emergencies which has preceded it. In going over it, the idea occurred to us that it would be a very useful text-book for grammar or high schools.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS. Vol. I, No. 2, February, 1889. This volume embraces: Gonorrhœal Infection in Women, by William Japp Sinclair, A.M., M.D.; on Giddiness, by Thomas Grainger Stewart, M.D.; and Albuminuria in Bright's Disease, by Dr. Pierre Jaenton. In all, 260 pages. Price, $1.00. (The series is published monthly, at $10.00 per annum.)

Vol. I, No. 3. Contents: Neurasthenia, and its Treatment, by Dr. H. Von Ziemssen; Antipyresis and Antipyretic Methods of Treatment, same author; The Tongue as an Indication of Disease, by W. H. Dickinson; On the Treatment of Cystic Goitre, by T. M. Hovell, F.R.C.S.; New Remedies, from 1878 to 1888, by Dr. O. Canquil; and the index for Vol. I. Dr. Dickinson's paper is illustrated by a number of cuts and four colored plates.

Vol. II, No. 1. Contents: On Diabetes and its Connection with Heart Disease, by Jacques Mayer, M.D.; Blennorrhœa of the Sexual Organs and its Complications, by Dr. Ernest Finger.

PHYSICIAN'S LEISURE LIBRARY. THE RADICAL CURE OF HERNIA. By HENRY O. MARCY, A.M., M.D., L.L.D. Detroit, Michigan: Geo. S. Davis.

Hernia is a subject interesting at all times, both on account of its frequency and its obstinacy. The author discusses this trouble, *ab initio*, in a readable and able manner.

Numerous experiments on animals and a number of operations on patients have convinced him that the best operation is the open wound operation under strict antiseptic precautions, and with sutures of gut.

THERAPEUTICS FOUNDED UPON ORGANOPATHY AND ANTIPRAXY. By WM. SHARP, M.D., F.R.S., etc. 8vo. pp. 203. London: Geo. Bell & Sons, 1886.

This book is arranged in the form of essays, six in number.

For a motto the author takes the quotation: "The sick man dies of his doctor," and, as he proceeds, attempts to prove, successively, that the theory and practice of medicine of to-day is founded on principles essentially wrong, and its followers are little better than charlatans; that homœopathy is defective, but has pointed out the true path, and that a peculiar system, which he has founded and called antipraxy, is destined to become the medicine of the future, and has in it "laws" which are unchangeable and uniform, and which in all cases govern the actions of drugs.

"Antipraxy" has for its foundation what the author considers to be a great law-fact, viz., that the action of all drugs on the healthy individual in small doses is opposite to their action when taken in large doses—that is, that a drug which in large doses stimulates, will, in a small dose, depress.

What constitutes a large and what a small dose he believes must be separately determined for each drug, but his work shows a wonderful preference for such doses as the "third potency"—that is, the one-millionth of a grain.

He says that medicine is "without principles and therefore without science," and, in the next breath, mourns that "if there has been a discovery of laws and principles the announcement of them . . . is treated with indifference if not with scorn."

Again, he boldly decries the practice of using the knife in cases of epithelioma of the tongue, but fails to tell us how otherwise to stop its progress.

Such statements as treatment of a disease by "lowering life" on one hand or "stimulating" it on the other, only "help disease to kill," cause us to wonder if the author ever saw a marked case of plethora or one of typhoid fever.

His theories are but a faint excuse for the follies of homœopathy, and, among other curious recommendations, he suggests as good treatment for poisoning by arsenic, a small dose of arsenic.

It no doubt is well that as he says antipraxy and its practical application have been so far confined to his hands.

The whole work is extremely visionary, and when in its pages we find "there is little progress" in medical knowledge at this time, we can but wonder if the author has spent the last quarter of a century in central Africa.

Pamphlets.

What is the Normal Posture for a Parturient Woman? By A. F. A. King, M.D.

A Brochure on the Hypodermic Treatment of Internal Hemorrhoids. By Q. A. Shuford, M.D., Tyler, Tex.

Dreams, Sleep, and Consciousness, a Psychological Study. By George M. Gould, M.D.

Catalogue of the Pennsylvania State College. Center Co., Pa., 1889. This catalogue shows a flourishing condition of this worthy and excellent Institution.

Syllabi of Studies Pursued in the Philadelphia Dental College, and Hospital of Oral Surgery.

Medical Examiners' Bill. By W. B. Trites, M.D. From *Hahnemannian Monthly.*

The Twenty-first Annual Report of the Midnight Mission. Mission House, No. 919 Locust Street, Philadelphia.

This is a most commendable charity, and has done good work. The report shows that out of 1218 cases received during the twenty-one years, 941, or 78 per cent, have been benefited, many of these restored to home and friends. This large percentage in a class of people so low makes comment on the beneficence of such an institution unnecessary.

Temperature and Atmospheric Humidity and their Relations to Health and Disease. By J. M. Anders, M.D., Phila.

First Annual Report of the Board of Governors of the Gynecean Hospital to their Contributors. Hospital, Corner of Eighteenth and Hamilton Streets, Philadelphia.

Placental Development. By Henry O. Marcy, A.M., M.D., LL.D., Boston, Mass.

The Histology and Surgical Treatment of Uterine Myoma. By Henry O. Marcy, A.M., M.D., LL.D., Boston, Mass.

The Climate of the Southern Appalachians. By Henry O. Marcy, A.M., M.D., LL.D., Boston, Mass.

Lichen Ruber as Observed in America, and its Distinction from Lichen Planus. By R. W. Taylor, M.D., New York.

The Cortical Localization of the Cutaneous Sensation. By Charles A. Dana, A.M., M.D., New York.

Annual Announcement, Department of Medicine and Surgery, University of Michigan, 1888–89

Explanatory Notes on Dr. Keyes' Investigation of Electrolysis. By C. R. Dickson, Kingston, Ont.

On the Relation Between the General Practitioner and the Consultant or Specialist. By L. Duncan Bulkley, A.M., M. D., New York.

Postero-lateral Spinal Sclerosis or General Ataxia. By W. Everett Smith, A.B., M.D., Boston, Mass.

Pulmonary Consumption Considered as a Neurosis. By Thomas J. Mays, M.D., Philadelphia.

A Case of Hodgkin's Disease, accompanied with a possible resulting Paraplegia. By Lewis H. Adler, Jr., M.D., Phila.

Biennial Message of Richard J. Oglesby, Governor of Illinois, to the Thirty-sixth General Assembly.

The Relation of Education to Insanity. By Geo. D. Stahley, A.M., M.D., Easton, Pa.

Graves' Disease. By William C. Baily, M.D., Albion, N. Y., President Central New York Medical Association, 1888–89.

Message of Governor Robert Taylor to the Forty-sixth General Assembly of the State of Tennessee, 1888.

Report for 1888 of the Children's Sea-shore House, at Atlantic City.

Improprieties of Dress an Important Etiological Factor in Many of the Diseases Peculiar to Women. By Sebastian J. Wimmer, M.A., M.D., of St. Mary's, Pa. Reprint from THE MEDICAL REGISTER, November 24, 1888. 10 pages.

The many evils arising from the use of corsets and tight lacing are graphically set forth. While there is nothing new presented, old truths appear in a fresh and attractive garb which cannot but impress upon the reader the necessity for a reformation in the modern mode of attirement.

Gleanings.

BOUCHARD points out that in certain diseases of the spleen characterized by increase in size (due to congestion) a soft, prolonged murmer may be heard over that organ. He has proved its presence in five cases accompanying cirrhosis of the liver.—*La France Medicale.*

WICKS reports a case of acute tympanites, occurring in the sixth month of pregnancy, in which the symptoms were so urgent that the abdomen was punctured in four places with a trocar. Immediate relief ensued, but labor continued.

CHEADLE considers the claim of tonsillitis to be ranked as one of the rheumatic series to be well established. In the list of rheumatic affections he mentions anæmia, erythema, exudativum, and nodosum, purpura, chorea, subcutaneous tendinous nodules, and pleurisy.

PICRIC ACID IN ECZEMA.—Picric acid has recently been employed by Cerasi, in the treatment of eczema impetiginosum, with considerable success. Seven cases of this disease, affecting the face and scalp, were rapidly cured by local applications of the acid. The ages of the patients were from two to four years. —Merck's *Bulletin.*

EHRLICH'S TEST.—Howard Taylor calls attention to the importance of Ehrlich's test in suspected typhoid fever. It is made as follows: A, a saturated solution of sulphanilic acid in dilute (1 to 20) hydrochloric acid. B, a 5 per cent. solution of sodic nitrite in distilled water. These must be freshly prepared; the second one not lasting over a week. In using the test, about twenty-five parts of A are added to one of B. Mix with this an equal bulk of the suspected urine, and render it alkaline with strong ammonia.

With normal urine the only change, the usual change, is a deepening of the color to a sherry or vinegar-brown. In fevers others than typhoid the color is a darker brown than in healthy urine. With typhoid urine the color rapidly becomes red, varying from a bichromate of potassium solution tint to a rich port-wine color. The froth produced on shaking has a characteristic pink tint.

This reaction is not always given until near the end of the first week. It may cease when the morning temperature has returned to normal. Otherwise, it is present in every case.

Unfortunately, it seems to be not rarely present in other conditions. It is occasionally present slightly in healthy urine; very rarely and very slightly. In several cases of acute and chronic Bright's it has been detected; also in one case of hysteria, one of chorea, two of diabetes mellitus, and one of polyuria. It is common in measles, sometimes present in acute and chronic phthisis, though never in acute general tuberculosis; said to be sometimes in pneumonia and diphtheria, and twice in acute rheumatism.—*Lancet.*

VOMITING OF PREGNANCY (*Hubert*).—

℞.—Iodide of potassium	1½ drachms.
Tinct. of iodine	6 drops.
Distilled water	4 ounces.—M.

Three tablespoonfuls a day.—*Gazette Médicale de Montreal.*

LINIMENT FOR NEURALGIA.—

℞.—Comphorated alcohol	90 parts.
Ether	30 "
Tincture of opium	6 "
Chloroform	20 "—M.

To be applied on flannel.—*Courier Médicale.*

INJECTION FOR HYDROCELE (*Richet*).—

℞.—Bichloride of mercury	18 grains.
Distilled water	1 pint.—M.

Six to eight ounces is to be injected and about half the quantity is allowed to remain in the scrotum, when it will be absorbed by the subsequent inflammation.—*Courier Médicale.*

COMPOUND WINE OF CREASOTE (*Frænkel*).—

℞.—Creasote	3 drachms.
Tincture of gentian	1 ounce.
Alcohol	8 ounces.
Sherry wine, q. s. to make	1 pint.—M.

Two or three tablespoonfuls a day in tubercular phthisis when the temperature is not very high and when the bacilli are not yet very abundant.—*Union Médicale.*

NAPHTHOL IN PYOTHORAX.—Bouchard, in two cases of pyothorax, used intra-pleural injections of naphthol with very good results.

He used naphthol, 5 parts, alcohol, 33 parts, and distilled water, enough to make 100 parts. Of this, he injected from half a drachm to a drachm twice a day.

As soon as the solution reaches the pleural cavity, the naphthol is precipitated, but part of it is redissolved again in the inflammatory exudate and sterilizes the contents of the pleura. No operation for empyema was necessary.—*Wiener Med. Presse.*

THE MICROBE OF ECLAMPSIA.—Blanc (*Arch. de Socologie*) states that there exists in the urine of eclamptic patients a microörganism, whose pathogenic action is shown by experiment to be as follows:

1. *General Convulsions.*—In rabbits these convulsions are followed after a brief delay by the death of the animal. Pregnancy constitutes for them a manifest predisposition.

2. Intense inflammatory swelling at the level of the points inoculated. This inflammation is produced in animals which have withstood the grave general phenomena of the beginning; it is soon followed by spacelus. After the cure of these accidents, the animals enjoy towards the same microbe an immunity which is great, but not absolute.

3. Different incidents of the infectious order; miliary abscess, phlebitis, fever.

4. Renal determinations of variable gravity and albuminuria.

THE Cincinnati *Lancet-Clinic* contains a report of a case in which a child of three years of age was given, by mistake, a teaspoonful of tinct. opii. deodorat. Two hours afterwards a physician was summoned, and he succeeded in saving the child's life by the use of emetics, coffee, and atropia.

REID ALEXANDER, M.D. (*Kansas Med. Jour.*), reports a case of successful triple synchronous amputation of both legs and one arm. The patient was a brakeman, and was run over by the cars. The right arm was removed three inches below the elbow, the right thigh at the junction of the upper and middle thirds. and the left leg at the junction of the middle and lower thirds. The patient was discharged in eight weeks.

NOMA.—Yates and Kingsford (*Lancet*) report three cases of facial gangrene, treated successfully by sublimate applications. The first case, aged three years, convalescing from measles, had been treated with iron, good diet, stimulants, and nitric acid, but the gangrene still spread. Immediate improvement and an ultimate cure followed the use of sublimate solutions, one part to five hundred. The other cases were similar.

GRAVES' DISEASE AFTER REMOVAL OF NASAL POLYPI.—Dr. Simon read before the Clinical Society of London a paper on a case of this kind. A day or two after removing several polypi from the nasal cavity there occurred exophthalmos of the right eye, but no increase in the size of the thyroid gland nor acceleration in the pulse-rate.

In view of the fact that in several instances Graves' disease has been known to disappear after intra-nasal operations, and as the polypi had returned, one of the members suggested that Dr. Simon had better remove them again, and perhaps this time the disease might leave.

EPITHELIOMA OF VAGINA AND VULVA.—Paul F. Mundé (*Am. Jour. of Obstetrics*), gives an account, illustrated with colored plates, of a case of epithelioma of the labium majas and one of the vagina. The latter is quite rare, only some twenty-six being recorded. He himself has seen two. The first was in a woman of twenty-four. The growth recurring after the first removal, he was compelled to perform a second operation, after which she remained well. In the present case the woman had been treated for a vaginal discharge for six months before he saw her. He found a "friable, spongy, easily bleeding mass the size of an orange, growing from the posterior wall of the vagina, not involving the cervix, and extending to about one inch from the vaginal orifice." The tumor was removed with the écraseur and its base cauterized. Two months afterwards she presented herself again, with a mass as large as, and much more offensive than, the one before, but as she had become cachectic, nothing could be done for her but to alleviate her discomfort and prolong her life for a time.

Medical News and Miscellany.

NOTE TO SUBSCRIBERS.—Those who have subscribed to two or more of the journals united in the present combination will have their subscriptions extended in proportion to the amount overpaid.

THE case of alleged yellow fever at Palmetto, Fla., turns out to be typho-malaria.

DR. WALTER LINDLEY, of Los Angeles, Cal., has been in Philadelphia on a visit.

PROF. H. A. KELLY has been elected to the Chair of Gynecology at Johns Hopkins University.

TYPHOID FEVER and diphtheria are widely prevalent in Northamptom and Lehigh Counties.

DR. CASPAR SHARPLESS has left the Philadelphia Hospital and gone to the Orthopædic as Resident.

A LICENSE for a baby farm has been issued to the Women's Charity Industrial Union, 612 South Eighteenth Street.

INDIANAPOLIS horses have the malarial fever. Many animals are dying, and thus far no remedy has been found.

A NEW disease called photo-electric ophthalmia is described as due to the continual action of the electric light on the eyes.

A WEIGHTY argument in favor of electric lights is that they do away with the danger to the rural visitor who blows out the gas.

A NEGRO was sent to the Municipal Hospital under the impression that he had smallpox, but proved to be suffering with pneumonia.

THERE were four hundred and twenty deaths in Philadelphia last week, of which five were due to scarlet fever, and seventeen to typhoid fever.

PLASTIC SURGERY.—The outer corners of the eyes of Turkish girls are often cut to render the eyes larger and more beautiful.—*Western Medicat Reporter.*

THE Canada *Medical Record* utilizes its reporting staff to test the samples left on its table. It graphically describes the results following the employment of a glycerin suppository.

SAMUEL C. HOOKER, Ph.D., proposes to furnish to the public a weekly statement concerning the state of the Schuylkill water. Those already given show that the water is much better than is generally supposed.

DR. AND MRS. KERLIN, of Elwyn, sailed on the "Ohio," upon a six months' trip to Great Britain and the Continent. Dr. Kerlin has been for twenty-five years superintendent of the Pennsylvania Training School for Feeble-minded Children at Elwyn, which shelters seven hundred and fifty children. The Board of Managers requested him to make this tour in recognition of his long and valuable services, and for the purpose of enabling him to enlarge his means of usefulness to the school by visiting similar and cognate institutions in Europe.—*Press.*

IT may be that the phonograph will prove of value to the demonstrator of physical diagnosis. By its use, a typical, crepitant râle, a pleuritic friction sound, or an aneurismal bruit may be preserved and reproduced for the edification of successive classes of students. This will enable the teachers in cross-roads colleges to become quite independent of the clinics for their material.

ITALICISED WORDS.—Those who frequently underscore words in their articles should call to mind the words of rhetoricians, to the effect that the more italicised words the author uses the weaker is his writing; for they show that he has not skill enough to place his emphatic words in emphatic positions in the sentence, but must resort to the highly objectionable method of italicising them.

ONE of the most fashionable of Philadelphia physicians always kisses his hand when waving farewell to his wealthiest lady patients; but some of them were comparing notes the other day and found that for visits when he kissed his hand he charged $10, while for others he charged only $5.—*Times.*

We think we know him; and if so, the courtly grace with which he does it is worth $5.

COMMISSIONER TANNER has appointed the following Medical Examiners for Pensions: Pottsville, Drs. D. W. Bland, C. E. Quail and C. T. Palmer; Montrose, C. C. Halsey; Lewistown, J. P. Gethe and J. T. Mahan; Trenton, D. Warman and R. R. Rogers, Jr.; Pennington, E. L. Weling; Philadelphia, W. H. Hutt, J. P. Patterson, and J. B. Harmer; also J. S. Ramsey, C. B. Penrose, and S. Starr; Reading, A. G. Cresswell, F. K. Spang, and J. B. Sterley.

DR. BENJAMIN LEE, Secretary of the State Board of Health, has been appointed Commissioner for the United States to meet Commissioners for Delaware to fix the boundaries for the reservation which the latter State is to cede to the general government for the purpose of a thoroughly equipped quarantine station at Lewes. The government has set aside $75,000 for the new station, and with a thorough administration of affairs there and at the city quarantine station, near Chester, there will be little danger of yellow fever or cholera gaining a foothold in Philadelphia.

THE large catalogue of Medical Books and Journals issued by Dr. A. E. Foote, of 1225 Belmont Avenue, Philadelphia, has the same relation to the ordinary commercial catalogue as the Index Catalogue of the Library of the Surgeon-General's office does to the ordinary catalogues. It is now being issued, being complete as to Hygiene, Yellow and other Fevers; Obstetrics, Surgery, Anatomy, Practice, Urinary, Venereal, Brain, and Nerve, etc. When fully completed it will include over 1400 titles. It is sent free to every physician requesting it on headed paper, or by including his professional card. It will be found useful to any practitioner who thinks or writes. He issues similarly complete catalogues on Chemistry, Physics, Geology, Natural History, Mineralogy, and on all other branches of science.

BOSTONIAN COURTSHIP.

A man of modern science wooed
A maiden of accepting mood,
Who, dreading lest contagion might
Do mischief to her chosen wight,
With sol, bichloride washed her hair
And sponged her limbs and body fair.

She rinsed her mouth with "Listerine,"
And held, her snow-white teeth between,
A pad of antiseptic gauze—
Covering her nose, as well as jaws—
Which formed a sort of respirator
Between them and her "osculator."

But this reminds—I should have told
That these were things he'd taught of old,
With others which I may not tell, in
Regard to spots that germs might dwell in.
She was a wise professor's daughter
And practised all which had been taught her.

So this good medicine man, with pride
Clasping his antiseptic bride—
In disinfected murmur low
Asked "why she loved her doctor so?"
And, softly nestling down, she sighed,
"You're such a dear *old germicide.*"

—Boston *Medical and Surgical Journal.*

Apropos of the consolidation of journals to form The Times and Register, a publisher remarked to us: "Why don't you continue the three separately? *You* can get an advertiser *or* subscriber to patronize three as easily as one." The idea evidently was: Get the good will of a man and then "work him" for all he is worth.

Commendatory.—Tennessee now has a Medical Examining Board, and the Governor with singularly good judgmeot has given to the State Medical Society the privilege of recommending three members of this Board, he to "nominate the fourth regular practitioner. Elected in such a manner the Board is likely to be both competent and just.

Effect of Drainage.—A striking example of the grave importance of sanitation is found in Munich. An excellent system of drainage works was finished in 1881; and, according to the *Sanitary News*, the annual deaths from typhoid fever, which had numbered 245 up to 1880, were reduced in 1881 to 40, the yearly average since that time.

Dr. Hummel has organized another journal entitled *The Pennsylvania Monthly;* under the auspices of the University of Pennsylvania. Dr. Hummel is an enterprising publisher, and is now interested in *The University Medical Journal*, *The Annals of Hygiene*, *The Journal of Comparative Anatomy and Physiology*, and, we believe, a homœopathic journal.

Maternal Impressions.—Dr. St. Clair (*Med. Summary*) says in the course of an article on this subject that he once confined a white woman of a nearly black child, whose singular color the mother explained by saying that she had been chased by a negro when she was eight months with child. The doctor thinks that she might have added with truth "and he caught me too."

Medical Society of the State of Pennsylvania.—Fortieth Annual Session, to be held at Pittsburgh.

First Day, *June* 4, 10 A.M.—The President, Dr. J. B. Murdock, will call the Society to order. Prayer, Rev. David Jones. Presentation of Register of Delegates, Dr. W. B. Atkinson, Secretary. Address of Welcome, Dr. E. A. Wood, Chairman of the Committee of Arrangements. Report of Programme. Introduction of Foreign Delegates and Visitors. Report of Delegates to the American Medical Association and other societies. Report of Permanent Secretary. Report of Corresponding Secretary. Report of Treasurer. Report of Committee of Publication. Report of Medical Examiners of County Societies. Report of Committee on Medical Education. Appointment of Committee on Unfinished Business. Unfinished Business. New Business. Intermission at 12.30 P.M.

2 P.M.—Address on Medicine, Dr. J. C. Wilson, Philadelphia; Address in Hygiene, Dr. T. J. Mays, Philadelphia; Cases of Labor (340), Dr. J. M. Batten, Pittsburgh; Sarcoma of Choroid, case, Dr. Wm. C. Bane, Canonsburg; Calling on Counties for Names of Members of Committee on Nominations; Value of Measures over Medicines, Dr. J. Madison Taylor, Philadelphia; Unfinished Business; New Business; Adjournment at 6 P.M.; Address of the President, Dr. J. B. Murdock. at 8 P.M., in the Bijou Theatre.

Second Day, *June* 5, 9 A.M.—Naming Committee on Nominations. Address in Laryngology, Dr. Wm. H. Daly, Pittsburgh; Diet in Therapeutics, Dr. Solomon Solis Cohen, Philadelphia; Trephining in Traumatic Insanity, Dr. Samuel Ayres, Pittsburgh; Report of Committee on Clinical Research, Dr. John B. Roberts, Chairman; Report of Committee on Management of Pennsylvania Hospitals for the Insane, Dr. Samuel Ayres, Chairman. Unfinished Business. New Business. Recess at 12.30 P.M.

2 P.M.—Report of Committee on Nominations. Address on Surgery, Dr. John B. Roberts, Philadelphia; Pneumonia, Dr. James Tyson, Philadelphia; Ptomaines as the Factor in a Disease Class, Dr. E. A. Wood, Pittsburgh; Prolapsus of Rectum in Children, Dr. H. R. Wharton, Philadelphia; Ventilation of Cities, Dr. J. M. Anders, Philadelphia. Unfinished Business. New Business. Adjournment at 6 P.M.

Third Day, *June* 6, 9 A.M.—Address in Obstetrics, Dr. Frances N. Baker, Delaware County; Is Gestation Ever Prolonged? Dr. J. Milton Duff, Pittsburgh; Extra-uterine Pregnancy, Dr. M. Price, Philadelphia; Cocaine, Dr. Edward Jackson. Philadelphia; Report of Committee to Revise the Constitution of the Medical Society of Pennsylvania, Dr. Wm. M. Welch, Philadelphia, Chairman. Unfinished Business. New Business. Recess at 12.30 P.M.

2 P.M.—Address in Nental Disorders, Dr. Alice Bennett, Norristown; Sebaceous Glands, Dr. John V. Shoemaker, Philadelphia; Operation in Abdominal Diseases, Dr. J. M. Baldy, Philadelphia; The Typhoid State, Dr. J. Chris Lange, Pittsburgh; Report of Committee on Medical Examiners, Dr. L. F. Flick, Chairman; Report of Committee to Confer with State Committee on Lunacy, Dr. H. C. Wood,

Chairman. Report of Committee on Pharmacy, Dr. J. W. Holland, Chairman. Unfinished Business. New Business. Adjournment at 6 P.M.

Fourth Day, June 7, 9.30 A.M.—Reports of Committees. Unfinished Business. Inauguration of President-elect. New Business. Final adjournment at 10.30, to Visit Dixmont Insane Asylum.

Entertainments for the Fortieth Annual Session.—Tuesday, 8 P.M., President's Address, Bijou Theatre. 9 to 12 P.M., Reception at Monongahela House by the Allegheny County Medical Society. Wednesday, lunch at West Penn Hospital, 5 P.M.; Reception by Mr. and Mrs. M. K. Moorehead, 9 to 12 P.M. Thursday, lunch at Mercy Hospital, 12.30 P.M.; excursion to Bessemer Steel Works, nine miles up the Monongahela River, with lunch by Carnegie Phipps & Co., 5 P.M. Friday, excursion to Dixmont, immediately after adjournment, about 11 A.M.

IN regard to the case of trance at Attica, N. Y., we have received advices from a prominent physician of that place, saying that the woman is a humbug. The newspaper accounts indicate rather an ordinary type of hysteria. We have taken the trouble to investigate a number of the recentiy reported cases of trance, but have as yet not succeeded in locating a genuine cases.

THE HIGHEST DEATH-RATE.—According to *Annals of Hygiene* the deaths from typhoid fever per 100,000 are: in New York, 23.5; Baltimore, 32.2; Boston, 40.9; Chicago, 45.1; Philadelphia, 76.5. It further says that Philadelphia has a larger typhoid fever death-rate than any other city in the world, and traces this to the polution of the Schuylkill by sewage from cities and towns above it, including the sewage of Laurel Hill Cemetery with its 80,000 silent inhabitants.

A VERY well-written letter in the *Ledger* describes the singular prevalence of alcoholism, and of deaths from that cause, in the summer of 1887, as compared with 1886 and 1888. From five deaths referred to this cause in the first quarter of 1886 there was a steady increase which culminated in the third quarter of 1888 (which was an unusually hot summer), when there were sixty-one deaths; the number falling to seven for the corresponding quarter of 1888. The writer thinks there must be a special tendency to death from this cause in very hot weather or else some deaths from sunstroks were attributed to alcoholism.

As the victims of hay fever are beginning to collect funds, etc., for their annual migration to high latitudes, we have a suggestion to offer them. Let a ballon be constructed, large enough to accommodate a goodly company, and have it anchored over some convenient spot, say Boldt's new Stratford House, so that the comforts of life may be secured and health enjoyed without the trouble and expense of a long journey and the discomforts of mountain hotels. If the weather becrne threatening, the balloon could be lowered until the danger is past. Urgent business could be attended to; telephonic communication with the family kept up; and, in short, the whole scheme presents many advantages.

BROTHERLY LOVE exists among the St. Louis doctors.

THE adoption of the separate system of drainage has reduced the death-rate of Salisbury from 40 per 1000 to 16.

ABSINTHE drinking is on the increase in St. Louis. However, with ten medical colleges in their midst people must do something to keep up their spirits.

APPLICATION has been made to the courts for a charter for the Charity Hospital for Women. Among the directors are Drs. Henry Leaman, W. L. Boyd, and C. P. Noble.

TAMA CITY, Iowa, has been suffering from the death of thousands of fish in the Iowa River. The water has killed numbers of cattle, and made many persons sick. The trouble is thought to be due to the refuse from the glucose works, which will probably be closed.—St. Louis *Globe-Democrat.*

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 21, 1889, to May 27, 1889.

FORWOOD, WILLIAM H., Major and Surgeon. The leave of absence, by direction of the Acting Secretary of War, on Surgeon's disability, granted in S. O. 35, April 8, 1889, Department of Dakota, is extended one month. Par. 13, S. O. 118, A. G. O., Washington, May 22, 1889.

MIDDLETON, PASSMORE, Major and Surgeon. Will, as soon as practicable after his arrival at Fort Trumbull, Conn., proceed to Fort Warren, Mass., and report for temporary duty until the return of the post Surgeon from detached service with batteries of the Fourth Artillery, ordered to Atlanta, Ga. He will then return to his proper station, St. Francis Barracks, Fla. Par. 2, S. O. 113, Headquarters Division of the Atlantic, Governor's Island, N. Y. City, May 18, 1889.

MCELDERRY, HENRY, Major and Surgeon. Leave of absence for one month, to take effect upon completion of his duties as a member of the Army Medical Examining Board, in New York City, is granted. Par. 4, S. O. 117, Headquarters Division of the Atlantic, Governor's Island, N. Y. City, May 23, 1889.

PATZKI, J. H., Major and Surgeon. Leave of absence for twenty-one days is granted. Par. 1, S. O. 44, Headquarters Department of Arizona, Los Angeles, Cal., May 18, 1889.

RAFFERTY, OGDEN, First Lieutenant and Assistant-Surgeon. Ordered with troops, for field practice, to Galveston, Tex., where troops will camp for such time as may be hereafter directed. Par. 1. S. O. 29, Headquarters Department of Texas, San Antonio, Tex., May 13, 1889.

Changes in the Medical Corps of the U. S. Navy for the week ending May 25, 1889.

HENEBERGER, L. G., Passed Assistant-Surgeon. Detached from the "Thetis," and ordered to the "Iroquois."

HESLER, F. A., Assistant-Surgeon. Promoted to Passed Assistant-Surgeon.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service for the two weeks ended May 25, 1889.

HUTTON, W. H. H., Surgeon. To proceed to New Orleans, La., and inspect unserviceable property, May 25, 1889.

PURVIANCE, GEORGE, Surgeon. Detailed as Chairman Board of Examiners, May 22, 1889.

AUSTIN, H. W., Surgeon. Detailed as member Board of Examiners, May 22, 1889.

GODFREY, JOHN, Surgeon. Detailed as Recorder Board of Examiners, May 22, 1889.

GUITERAS, JOHN, Passed Assistant-Surgeon. Resignation accepted, by direction of the President, as tendered, to take effect April 30, 1889, May 11, 1889.

ARMSTRONG, S. T., Passed Assistant-Surgeon. Granted leave of absence for thirty days, May 11, 1889.

Clinical Lectures.

ON THE NEWER TREATMENT OF DISEASES OF THE NERVOUS SYSTEM.

(Delivered at the Hôpital Cochin, Paris, France)

BY DUJARDIN-BEAUMETZ.

(Reported by THOMAS LINN, M.D., Paris)

GENTLEMEN: In our last lecture we spoke about the progress that had been made in the treatment of nervous diseases, those relating to the spinal cord in particular. We showed the new suspension treatment, and mentioned the advantages it had. To day let us take up the medicinal means we have now in use, that will allow us to combat the acute lancinating pains which the patients so often have who suffer from spinal cord troubles. These *fulgurating* pains, as they are called, are perfect torture to these poor patients, so that you see at once the importance of meeting them with proper therapeutical measures. Thanks to the introduction of several new remedies, we have made considerable progress in treating these pains. These are the analgesics and antithermic drugs. Only a few years ago, we had but two methods of treating these paroxysmal pains. One was the application of cold or heat; the first as ice, and the last the actual cautery. We had besides hypodermic injections of morphine, but as I said in my book on "New Medication," "the longer I live in medicine, the less I am disposed to use opium;" not but that I admit it to be superior to all the analgesics; but I find that its use often brings about morphinomania—a social vice that is worse than alcoholism. Allow patients to take morphine for three or four weeks, and they will continue it forever; even physicians do not know enough to stop it in time, and become themselves afflicted with the morphine habit. Morphine, it is true, takes away pain, but it brings on the congestive phenomena of anæmia, and suppresses the urine, so that we should reserve its use for those cases of incurable diseases that have reached their last term, such as cancers and other serious maladies.

There is then a considerable interest attached to the proper use of the newer analgesics, so that morphine can be put to one side; and the new agents that have an action upon pain and have no particular contraindications can be used in its stead. These newer medicines all come from what is called the aromatic series that has furnished the antithermics, the antiseptics, and now gives us the most powerful analgesics, that are equal, if not superior, to those that are derived from opium or belladonna.

I shall first of all speak to you of antipyrin, as it is the best known of this group. It had up to the time of Germain Seé been considered as an antithermic, to be used in fevers only. The great advantage that antipyrin has over the other medicines of its class is that it is very soluble while the rest are almost insoluble. This allows of the use of antipyrin in sev-

eral ways. It, however, has the inconvenience of producing a form of rash, similar to scarlatina, in certain persons who use it. This happens with antipyrin when given in doses that are above four or five grammes a day, and it is more often seen in children than in adults, and in women than in men; this can be noticed when using it for chorea. Here a peculiar eruption is sometimes produced, but it is not at all dangerous. You will ask, what is the best way to give antipyrin? There are three methods in use: by the stomach, by the skin, and by the rectum; this last in injections or in suppositories. It may be given in wafers, but it is more effective when given in solutions. When the wafers are used, give a gramme night and morning; when the solution, the following formula is useful:

℞ —Antipyrin . . . . . 10 grammes.
Divide in ten doses and dissolve one in a glass of sugar and water, to which may be added a little rum or Kirsch, which will take away the odor of benzine that antipyrin usually has.

As a rule, a gramme of this drug night and morning is well supported by most patients, but sometimes the secretion of gastric juice is interfered with, or at least it becomes very acid. This bad effect can easily be remedied by using alkaline solutions in prescribing antipyrin in such cases, or simply ordering it to be dissolved in a glass of Vichy water, which may be sweetened.

Per rectum, antipyrin can be given in rectal injection, but the suppositories are better on account of the fact that these nervous patients cannot keep a rectal injection in. The following is a formula for these:

℞.—Antipyrin . . . . . 1 gramme.
Cacao butter . . . . . 5 grammes.
Wax, q. s.
M.—F. one suppository.

To use under the skin, as antipyrin is soluble you can make all sorts of solutions; but if equal parts of water and the drug are used, the solution will be very painful. It is better to use a solution like this:

℞.—Antipyrin . . . . . 5 grammes.
Boiled water . . . . . 15 grammes.

Then you may make two or even three injections of this, at the same sitting, so as to give the dose you wish; and this method is much better than that of injecting stronger solutions, which so often cause abscesses. Again you may add hydrochlorate of cocaine, if the injections are painful, as follows:

℞.—Antipyrin . . . . . 5 grammes.
Aquæ . . . . . 15 grammes.
Cocain. hydrochlor. . . . . 0, 15 centigrammes.

But I do not wish to speak of all the applications of antipyrin. At the same time I should tell you the end we have in view in using such drugs. As all these new medicines come out we should seek for and study their indications. Antipyrin has one clear and important one; it is for congestive neuralgias, megrim and congestive pains in the head. This is its best field of action. Then, again, in diabetes, to prevent polyuria. It acts on the superior portion of the spinal cord and diminishes the excitability of the medulla, and by that action the painful symptoms not only of the cord but also of the brain itself. It is in this way that it brings about a fall of temperature; that is, by acting on the thermic centers contained in the brain.

I now take up a medicine that is not so well studied, that is acetanilide, obtained by the action of acetic acid on pure aniline. Studied first by Hepp and Kahn, of Strasburg, who showed us its antithermic properties, and gave it the name of antifebrin, it was also first of all applied as an antithermic.

Prof. Lepine, of Lyons, then showed that it possessed an analgesic power; and I first spoke of its use in 1887, as a sedative to the nervous system. Two of my students then wrote on its use in the pains occurring in locomotor ataxia. It is a very active drug, but it also has its inconveniences, as it produces cyanosis; not that this blue color bothers the patient himself much, as he does not feel the slightest difficulty from it, but his friends and family get frightened when they see him turn blue. It is a poison and will kill animals when given in two grammes per kilogram dose. It acts on the nervous system and brings about analgesia and anæsthesia. It also acts on the blood and transforms the oxyhæmoglobine into methæmoglobine; while it brings about a fall of temperature by acting on thermic centers of the spinal cord.

Acetanilide is insoluble in water, so that it can be given in cachets or wafers only, in doses from 0.50–2 grammes per day. (It may be remarked here that the French always give the dose of a medicine per day, or per twenty-four hours, and rarely or never by single dose.)

Acetanilide should never be given in doses of over 0.50 at one time. It is soluble in alcohol, and Yvon gives the following formula:

℞.—Acetanilide . . . . . 5 grammes.
Elixir Garus. . . . . 170 " —M.
Sig.—Tablespoonful is a dose.

This solution is an agreeable preparation, but as alcohol is always to be avoided, when possible, it is well to use the cachets in preference.

The cyanosis, of which I spoke, is not always seen, even when considerable doses of the drug are given; and it seems to depend more or less on the activity of the kidneys in the patient, or, again, on the respiratory power of his blood. However, one can give this medicine for years without danger. A German author cites the case of a patient who took in a year as much as four hundred and ninety-five grammes without the slightest inconvenience. I have also kept up the use of acetanilide in epilepsy for years without danger. What are the advantages of this medicine? Well, if it was not so insoluble and did not produce cyanosis that frightened the patient's friends, it would be the best of the analgesic medicines. It is certainly the most powerful, in certain cases, where no other drug will act, especially in these fulgurating pains of locomotor ataxia.

Also, in neuritis, and in those pains that are brought about by compression of the nerves; but the cyanosis has frightened the doctors so much that it is now almost given up for other drugs of the same series. In this hospital service we have

had a very large number of cases of ataxia, and we have been able to relieve their lancinating pains with this drug, in doses of one and one-half grammes per day. In a patient that I have in town, who spoke of killing himself, from the pain that came on in violent paroxysms, I was able to stop the pains; and while the family did not want the medicine continued, owing to the cyanosis which set in and frightened them, the patient himself insisted on having the medicine, as he preferred being blue to having the intense gnawing pains. In treating epilepsy, I have made three cures by the use of acetanilide, which I still continue; but I admit numbers of failures. However, the success I have had, I find is in cases where they could not take bromides. In one case as much as fifteen grammes of bromide of potassium were given per day, without stopping the attacks, and yet acetanilide cured the case. So that you may try it in those cases which are not influenced by the bromides.

Original Articles.

AN EXPERIENCE IN INTUBATION.

By LAMBERT OTT, M.D.,
PHILADELPHIA.

THE practising physician often and justly frowns at novelties in the treatment of diseases, especially when after very superficial observations they are vaunted before the medical public; but he that decries intubation as invented and practised by O'Dwyer must certainly be a very careless individual. I had some very embarrassing accidents in my first cases, which probably could have been avoided had I known in what particular to be watchful; therefore, my purpose in offering the details of a limited experience, is to suggest to the ill-trained beginner how to evade troublesome incidents likely to occur when intubating for the first time.

Intubation is not a difficult operation to one versed in the anatomy of the parts, is easy to the cool, self-possessed man, and most difficult to one nervously excited during the manipulation. I have often met Dr. Montgomery, who has intubated more cases than any one physician in Philadelphia, and I attribute his dexterity to his remarkable coolness and making haste slowly, the latter condition being a *sine qua non* to the success of the operation.

The following are the instruc ions usually given: The child is held upright in the arms of a nurse, and the gag inserted in the left angle of the mouth, well back between the teeth, and opened widely; an assistant holds the head, thrown somewhat backward, while the oper tor inserts the index finger of the left hand to elevate the epiglottis and direct the tube into the larynx. The handle of the introductor is held close to the patient's chest in the beginning of the operation and rapidly elevated as the canula approaches the glottis. The tube is then pushed downwards without using much force. It is then detached, then the thread is withdrawn, while the finger is kept in contact with the tube to prevent it being also withdrawn.

One wishing to intubate should familiarize himself with the anatomical relations of larynx and throat, and, above all, remember that in passing the finger the tongue sinks and carries the epiglottis down over the laryngeal opening, therefore, the operator has to lift the epiglottis from its prone position, and will not find it vertical as when the throat is passive. This apparently trivial error is made by beginners, consequently they pass the tube over the closed larynx into the œsophagus. In fact, it is madness for one to attempt the introduction of the tube unless his finger rests on the laryngeal rim and holds up the epiglottis.

The following cases are from my own practice, exclusive of a number seen in the practice of other physicians:

CASE I.—Male child, aged four and one-half years. Diphtheria; exudate on tonsils, croupy cough, no dyspnœa. Third day stenosis followed by cyanosis, when tube was passed with immediate relief. Removed tube on third day. Recovery complete, except a persistent aphonia lasting one month.

CASE II.—Male child, aged six years. Diphtheria; exudate on tonsils and fauces, croupy cough and dyspnœa. Third day signs of stenosis; intubated successfully. Tube removed on fifth day. Recovery. After the loop of thread was cut it was found twisted and had to be broken. This was done in a second case while the fingers held down the tube, which procedure I would advise rather than to annoy the child by trying to untwist it.

CASE III.—Female, aged five years, membrane on tonsils only. Second day stenosis. Intubated five o'clock one Monday morning with immediate relief. The child did well till the following Wednesday morning, just forty-eight hours after its introduction, when she had a spell of strangulation, as the mother called it, and soon after the cough and voice returned. I was very much disturbed, not knowing what had become of the tube. Just after its introduction I ausculted larynx and trachea and elicited a high-pitched tubular sound, approaching a whistling. As the voice had measurably returned, I felt that the tube had either passed further down into the trachea or was coughed up and swallowed. Auscultating over the same region now gave a low-pitched, clear tubular sound, from which I concluded it had been swallowed, as it proved to be, passing in four days. The cough during the presence of the tube is distinctly tubular, and the moment you distinguish a vocal cough the tube has been displaced. The stenosis in this child did not return.

CASE IV.—Female, aged fourteen years, croupy cough, slight dyspnœa, and no membrane visible. On the fourth day stenosis became so alarming that I passed the tube; attempted its extraction on the fifth day, when I found the head of the tube nearly buried in swollen mucous membrane, which hindered me very much in its removal. Recovery was complete. At no time did membrane appear in the throat.

CASE V.—Male, aged fourteen years, diphtheritic stenosis. Intubated and removed tube on fourth day. Recovery.

Thus far all my cases have recovered, and this I attribute to the fact that none of them were grave forms of diphtheria with constitutional involvement. Removal of the tube is the most difficult part of the operation. Observing the following rules will facilitate matters. The head is held slightly inclined backward, pass the extractor guided by the index finger resting on the head of the tube and holding back the epiglottis. After the blades have been fixed, gently withdraw the instrument, but if the finger, still in position, does not feel the tube rising out of the larynx, then the expanded blades are not in the tube but scraping the pharyngeal walls. It is most important to retain the finger after the extractor is in proper position, not only to guide you as before mentioned, but to follow the tube and prevent it falling back in the throat. When the head of the tube is embedden in swollen mucous membrane its removal will be found most difficult. It has been suggested by an experienced operator that the child be held with the head down and the trunk concursed with a few rapid strokes, the same procedure so highly recommended in removing foreign bodies from the larynx and trachea. This writer claims that the tube is sometimes entirely removed or coughed out, or partially lifted so that the extractor can be easily applied. The thought occurred to me that anæsthetizing throat and larynx as far as practicable with a cocaine spray, would give the operator more latitude and less reflex obstruction, thus enabling him to seize the tube. The following points may be of interest: Always use a fine silk string which will play freely in the eye of the tube, and should it become twisted break it.

To feed an intubated child will tax the ingenuity of the physician. Most of them refuse everything but brandy and water until the tube is removed. The yelk of an egg and anything of a gelatinous consistency is easily swallowed. Two of my cases took nothing but water and brandy for six days. The longer the tube is in the better they swallow. I found invariably a great repugnance to milk. In four cases I had to discontinue all medication except a steam spray of lime water, which was used with signal benefit when the secretions became tenaceous and were not readily forced through the tube.

Do not worry the child with repeated throat examinations unless it can be done with his acquiescence.

Before introducing the tube be certain to have the gag well back and firmly fixed between the jaws. Heeding this precaution will save the operator the mortification of repeated futile attempts. In one case I had a single young lady to hold the head and just as I was about to fix the tube in the larynx she fainted, the child's head became unmanageable, making the circumstance quite painful; therefore, when medical aid is not at hand choose an elderly person to assist.

In Waxham's book on Intubation he has an illustration representing the operator standing. This I consider a bad position for the beginner, who should be seated close to his patient, as he can readily assume the standing position when necessary.

HUNTING THE GERM OF YELLOW FEVER.

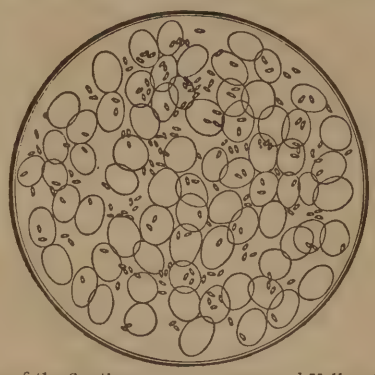
By FRANK S. BILLINGS, M.D.,

(Director of the Patho-Biological Laboratory of the State University of Nebraska.)

[Continued from page 105.]

Examination of Tissues for Microörganisms.

COVER-GLASS preparations made from alcoholic material as described later in the text—magnifying power, Zeiss ocular O oil immersion "$\frac{1}{20}$." But one microörganism present, and that sparsely represented. It is ovoid, of about the size of the organisms described as the cause of the Southern cattle plague



Germs of the Southern Cattle Plague and Yellow Fever.

when properly treated, and has a distinctly marked, clear center, with equally distinctly colored pole-ends. Where quite a conglomeration of tissue has been thinly spread upon the glass, these organisms are often seen end-on, and then look like cocci; cocci of the same character, size, and coloring reaction are also to be seen scattered through the specimen, but as the first described object is always to be seen more or less frequently represented, and as every competent patho-bacteriologist knows, or should know, that cocci represent a distinct phase in the development of this class of micro-etiological organisms, I feel justified in asserting that the specimen before me is infested by but one species, and that its members belong to the ovoid belted group of germs; which statement is also confirmed by the microscopic examination of properly stained sections of the organs above described.

Liver.—The above description will answer equally well as to the manner in which these germs present themselves to the eye. They are very small, and appear even smaller in the section than when seen in the smear preparation, which is but natural, unless we accidentally come across an individual presenting its horizontal diameter exactly to the eye of the observer, and so situated in the upper portions of the thinnest of sections as to be in direct apposition with the covering glass. In such cases, not only the peripheral outline but the sharply-colored pole-ends and the equally sharply outlined clear center can be distinctly seen. As said, these objects cannot be distinguished from cocci when they present themselves end on. They are sometimes to be seen in groups, sometimes in chains of several members, but I have not seen them forming long, connected threads as in the case of the swine-plague germs, especially in the kidneys. They are not only situated between th

parenchymatous cells but often in the bodies of the same. More especially are they represented in the smaller round cells present. No one but the merest tyro in the patho-biological examination of microscopic sections, no one competently versed in the technique of exact research can, or could, possibly overlook these organisms or mistake them for Kariokinetic figures or the peculiar phenomena presented by "mast-cells," both of which fail the clear outlines of the organisms, and in general have more affinity for the coloring substance.

They can be distinctly seen in the capillaries, sometimes almost filling the finest for a short distance, and then again extending along their course as single individuals, which conditions are only to be seen in fortunately made sections. In the larger vessels, when filled with coagulated blood, and a thin section of the coagulum has been fortunately made, they will be found more plentifully represented than in any other part of the section. In the preparation of sections by the carbol-fuchsin method, great delicacy of technique is required, as there is extreme danger of the formation of a very delicate precipitate, which the uninitiated might easily mistake for microörganisms, but which can be thoroughly removed by the lege-artistic treatment of the section before mounting. In the kidneys of the same individual the same microörganism is also profusely represented under the same conditions as those already described in connection with the liver. They were also present in the lymph-glands of the abdominal cavity.

"CASE II.—Edwin Sing, Norwegian; died at Hospital Garcini, October 24, 1888, at 3½ P.M. Autopsy at 4 P.M."

Liver.—Interstitial tissue diffusely increased, with marked sclerosis in those places where the larger vessels and gall-ducts take their course. While in some places it is markedly cellular, in others it is quite well organized, cellular structure being more or less wanting. In many parts the acini are distinctly outlined from each other by the presence of newly developed connective tissue, in which may be seen pieces of the ramifications of the neoplastic arterial capillaries. The walls of the larger arteries are much thickened. In many places the walls of the gall-ducts are so thickened that no lumen is to be seen. The parenchymatous cells are moderately swollen, and what is most striking is the entire absence of sharply coloring nuclei in the greater number. In others the nucleus is colored indistinctly, while in others again it cannot be seen at all. These latter cells are completely filled with a granulous substance, some of which is of a dirty yellowish color, and but slightly refracting, being very fine. Intermixed with this substance is a more coarsely granulous material, the individual granules of which possess a very strong degree of refraction.

Kidneys.—The general character of the microscopic lesions is the same as in the previous case; the complications of the stroma of the organ being slightly more pregnant, and the sclerotic condition of the walls of the larger arteries more marked. The engorgement of the subcapsular bloodvessels and those in the substance of the cortex is greater and the extravasations are more frequent and extensive. The parenchymatous changes in the tubes are not, in general, so marked, casts being wanting. Cover-glass specimens made from these organs in the same manner as before indicate exactly the same condition as to the microörganism present, except their more plentiful representation. Sections of the organs correspond thereto; the previously mentioned pigment in the cells of the liver seriously interfering with the view in many places, however, but in thin spots, more or less clear from the same, the germs may be distinctly seen. In the kidneys they are most profusely represented, especially in the intertubular tissue and spaces, and are to be seen with great distinctness, the section being most remarkably thin, as well as successfully colored. The variation in the extent of the uncolored belt which occurs during the process of evolution, and which causes a variation in the length of these organisms, is to be distinctly seen. The coagulum in some of the larger vessels is almost completely filled with these organisms. *No other organism is to be seen.*

"CASE III.—William Nelsen, German; died at Hospital Garcini, October 15, 1888, at 7 P.M., of yellow fever. Autopsy at 7½ P.M. the same day."

Liver.—Presents conditions exactly similar to those in the previous case, with the exception of a marked engorgement of the arterial circulation, as well as distention of the veins in places, and more complete sclerosis of the interstitial tissue surrounding the larger vessels, and less marked complication of the inter-acinous tissue. The kidney, on the contrary, while presenting similar parenchymatous changes to those described in the previous case, except in a more extreme degree, the granular character of the mass filling the tubes is excessively marked, cellular structure being almost entirely wanting as well as the nuclei. The most marked change is a diffuse complication of nearly all the capillary structure of the cortex, the walls of the arteries being so replete with nuclei as to make them almost as distinct as if injected. Accumulations of mono- and multo-nucleated round cells are present at many points of the bifurcation of the arteries, and especially in the vicinity of Bowman's capsule. The cortical portion is marked by a few engorged vessels and an occasional extravasation. In the medullary portion of the section at hand is quite a large vessel, with a ruptured wall surrounded by an extensive mass of extravasated blood.

Examination for Germs. — Smear-preparations of the above organs are especially characterized by their purity of representation, the absence of the coccoid form, and the remarkable clearness in which the belted structure and polar characteristics are presented. Examination of the sections confirms the previous statements.

"CASE IV. — Majin Marquez, Spaniard; died at Hospital Mercedes, July 8, 1888, at 1½ o'clock P.M. Autopsy at 4¼ P.M., same day."

Liver.—Sections of this organ are marked by the extreme degree of sclerosis of Glisson's capsule at those points where the larger vessels are collected, with extreme thickening of the walls of the gall-

ducts and encroachment upon their lumen. The veins are generally full of blood—many are markedly distended, which condition does not extend to the arteries as in the previous case. The complication of the inter-acinous tissue is greater and less cellular in character than in the previous case. There is also a diffuse complication of the intra-acinous connective tissue throughout the entire organ, with distinct encroachment upon the parenchyma, which, while less in quantity, has not undergone the same degree of acute degeneration, as in the previous case.

Kidneys.—The conditions of the kidney correspond more or less to those of the liver, those of a parenchymatous nature being of a minor degree, while those upon the stroma are more extreme, especially of the vascular system which are even more marked than in the previous case. The Bowman's capsule seems to be thickened. In some places the entire parenchyma has disappeared, its place being taken by granulation tissue. The cells bordering on the membrana propria are, in general, marked by clearly distinct nuclei, though an occasional one is wanting here and there. The balance of the contents of the tube is generally of a granulous character, though now and again a nucleus can be seen, and an occasional hyaline cast also; hemorrhages wanting.

Examination for Microörganisms. — Both smear-preparations and sections demonstrate the presence of the same microörganism as heretofore described with all the distinctness necessary.

"CASE V.—Soldier. Died of yellow fever, in Military Hospital, Havana, June 3, 1888. Autopsy five hours after death."

Liver.—Corresponds to that of the previous case but has a more marked sclerosis of the interstitial tissue in the great vascular spaces, with very distinct thickening of the walls of the arteries and almost complete occlusion of the gall-ducts. The inter-acinous complications are not, however, as distinctly marked, while the diffuse inter-acinous complication of the stroma is about the same.

Kidneys.—Diffuse complication of the stroma, a very slight degree of parenchymatous degeneration.

Examination of the Tissue of Above Organs for Germs. — Confirms previous statements in optima forma both in smear-preparation and section.

"CASE VI.—Soldier. Died of yellow fever, June 6, 1888. Autopsy three hours after death."

Interstitial complications in the liver less marked than in the previous case, being in general diffuse without any centralization at any particular point.

Kidneys.—Present the phenomena of acute parenchymatous inflammation with no complication of the stroma worthy of mention.

Microscopical examination of above tissue for bacterial organisms is but a simple confirmation of the results previously quoted, with this advantage, however, that the numerical representation of the germs is much more profuse than in either of the previous cases. A very large number of sections, and an equally large number of smear and covering-glass preparations were made from this material, *and it so happens that in but one of all these specimens* (most rigidly examined, not only once, but many times, and again most critically reëxamined when the previous notes were dictated) *was there any other form of microörganismal life present than that seen by Lacerda and Babes, as early as 1884, and again by me in 1887 in some of the same material, and also by Sternberg.* This exception consists of but two examples of a slim rod with rounded ends coloring diffusely and intensely and having about the dimensions of the tubercle bacillus. Whether or not this is the bacillus of Gibier I cannot say, as in none of the literature at my command is there a description of that organism sufficiently detailed to warrant the forming of even an approximate conclusion.

The other organism was present in every case, sometimes much more frequently represented but failing in none. In the Lacerda material it was, however, most profusely represented, as has been previously mentioned.

It will be remembered that both Sternberg and Gibier, more or less positively deny the constant existence of any organism in the tissues, though Sternberg admits this one distinctly and mentions others, while Gibier as distinctly says: "The blood, liver, spleen, and the kidneys have been found free from microbes."

With even more dogmatic positiveness, aye, with the effrontery of absolutism, I assert that this organism is invariably present in all the tissues examined by me, and that he who cannot demonstrate it is deficient in microscopic technique. I freely admit that it is difficult to demonstrate when very sparsely represented and only by isolated individuals scattered here and there among the cells, but if a small vessel filled with coagulated blood is cut appropriately there can be no possible excuse for not seeing them. Perhaps it may be that my more extensive experience with this class of germs and a more intimate acquaintance with their appearance in tissues, which probably exceeds that of any other observer, may be of value, but be that as it may, again I repeat *that not only in the Lacerda material but in a very large number of sections from the six Burgess cases this one organism is present, sometimes and often seen end-on, then looking like a coccus, sometimes lying full to the eye and then presenting its two pole-ends and clear middle piece, the latter varying much in extent in different individuals, sometimes seen obliquely, and again, if on the surface of the tissue and exposed to intense tinction, sometimes colored almost diffusely—but no matter how you see it it is one and the same organism.*

I do not, however, rely upon the examination of sections to make such a diagnosis. One is liable to be deceived if he does that. Hence, long ago I bethought me of a method by which we could handle alcohol-preserved material as easily and as surely as we can that absolutely fresh. After some experimenting I dropped upon the following plan, which can be promised to give as reliable results as those obtained from material taken immediately from a freshly killed animal. Naturally, the results will also depend on the freshness of the material when placed in the alcohol. In order to test its accuracy I have repeatedly killed an animal purposely

inoculated with a known germ and have at once put pieces of the organs in alcohol, while at the same time I made fresh smears from the blood and organs, preserving the slides. At a later date I have then treated the alcoholic material in the manner to be described and arrived at equally satisfactory results. It is scarcely necessary for me to say that this method is fully as reliable as the use of fresh material. In fact when the precautions are duly observed it may be more so, for if the material is properly removed, the piece washed externally in corrosive sublimate solution and then in distilled water, and from thence into absolute (or 95 per cent.) alcohol, the addition of any new organisms to the piece, other than those present in the animal, is next to an impossibility.

The Method.—The trouble with alcohol-hardened material has always been the uncertainty of what we saw even in the thinnest sections, in the case of such very minute organisms as those of the ovoid-belted-septicæmia producing group.

To avoid this: take a perfectly clean, cotton-plugged absolutely sterilized test-tube (or the requisite number), filter into it about the same quantity of a 1–10,000 caustic potash solution as you would use of gelatine or any other cultivating material. Sterilize this by heat. Let it stand until assured it is negative (when one is working much numbers of these tubes may be prepared at once and kept on hand). With sterilized forceps lift the piece of organ into the neck of its bottle and from its center, by other sterilized forceps, remove two or three small fragments and quickly place them in the potash solution, leaving them there some hours or until the alcohol is displaced. Then on carefully cleaned and sterilized glasses (if one thinks he needs so much care, and in such disputed cases as this it is unquestionably necessary) rub up these fragments or such parts as is necessary to give a coating, as with fresh material; dry in air, flame, color and mount.

[To be continued.]

VALVULAR DISEASES OF THE HEART.—Prof. Peter, in a clinical lecture at the Hospital Necker, calls attention to that which he considers an important point in valvular diseases of the heart. It is the intense feeling of suffocation which a hot bath is sure to produce. The reason is easy to understand. In all valvular disease compensation is established by two factors: the cardiac muscles for one part, and on the other the extremity of the circulatory apparatus, the muscles of the capillary bloodvessels. Consequently, If you plunge the body in hot water you dilate these vessels; the peripheral circulation is relaxed by the inertia of the capillary walls; one of the factors of the compensation is suppressed and the patient suffocates.

Another curious observation is that the lesion may be established without having been preceded by rheumatism. It may follow a fever of but short duration with slight pains in some portion of the body. Mitral insufficiency was found to follow in a young woman suffering from severe torticollis with fever of only twenty-four hours duration.—*La France Médicale.*

Hospital Notes.

JEFFERSON COLLEGE.

HYDROCELE.

THIS is not always the trifling trouble it is commonly supposed to be. Indeed, it is likely that in the majority of instances there is accompanying some disease of the cord or the testes. If the hydrocele is at all large, do not draw off all the contents on one occasion, but a little at a time, so that the sac may gradually contract and thus lessen the danger from septic poisoning through the entrance of air. This is the great danger. I have known of a number of cases in which septicæmia, gangrene, and even death have followed this simple operation. Indeed, I think that the only scientific method of treatment is thoroughly to lay open the scrotum so that the parts will be directly under the surgeon's eye. But if you intend to draw off the contents and inject some irritant, I would suggest that instead of diluting iodine, for instance, with say eight parts of water, and then injecting the solution, that you let the eight parts of water remain in the sac, and inject into it the pure iodine. You lessen by that much the danger of the entrance of air through squeezing out all the contents of an elastic bag. A few days after injecting the irritant the scrotum will probably swell up as large as it was before, but there is no cause for alarm—it will go down again when the inflammation subsides.

Here is a small hydrocele in which I shall simply make four or five punctures with a sharp needle, and the contents will gradually ooze out without any further operation.—*Allis.*

HARE-LIP.

This case of hare-lip was operated on last week. The division extended through not only the lip, but also the hard and soft palate, so it was a difficult and unpromising case on which to operate. You notice the little teat like projection hanging from the middle of the lip. That was made by freshening the two opposing edges, cutting the strips not entirely off, but allowing them to hang down. I will not snip that off, and I hope the parents will allow no one else to do it, for in the course of years considerable deformity will result from the fact that the normal tissues will grow faster than the cicatricial parts, and then when the child is ten, twelve, fifteen years old, this little projection can be utilized to remedy these defects in growth.

Hare-lip operations are exceptionally difficult for the reason that your very first one must be a success, or woe be to you! You cannot spoil one, throw it away, and try another. So be cautious with your knife and scissors. It is easy enough to snip a bit off, but no man can snip any on. Now about the pins and sutures. Instead of putting in the pins first, I put them in last. You can always see the scars left by pins which have been thrust transversely across the lip, and wound with figure-of-eight. After freshening the edges, I put in the stitches, beginning above. Any one of these can be taken out and put

in again if need be. After I have perfect apposition, I put in a pin, passing it from under the free border of one side of the lip diagonally up to the nostril of the opposite side. Sometimes I put in two. No noticeable scar is left by this proceeding, and in the case of a girl, especially, this little matter is of great importance.—*Allis.*

BOILS.

Here is a little child with a number of boils. The mother is unwilling to have them opened with a knife, and, indeed, I am better pleased that she is not; for I do not believe that incising a furuncle hastens its healing. It will give a patient some relief from the pain, but will do no further good. These boils are the expression of a depressed system. This child needs much that it has not and cannot get—nourishing food, fresh air, cleanliness, better home surroundings. From their looks I should think that both mother and child would catch a cold were they to take a bath.

Elixir of calisaya and iron would do well here. And add to each teaspoonful of elixir of calisaya from half a drop to a drop of Fowler's solution.—*Allis.*

CHANCRE.

This man is said to have a chancroid, but from the fact that it is just at the meatus and has an indurated feel, I believe it to be a chancre. The pus apparently coming from it really comes from farther up the urethra.

I find only one enlarged gland in the groin, but it is as yet too early for that sign. We will dress the sore with a little cotton saturated with plumbi acetat. gr. iij to ʒj, in order to reduce the imflammation, and besides that give some simple placebo till the rash comes out. If we begin mercury at once, the rash will probably not come out, and the patient is likely to conclude that he does not have syphilis. He will take medicine for a month or two and then disappear, only to come back one, two, or three years later with tertiary symptoms. I find that I get rid of the rash quickest by giving doses of blue-mass, guarded with from a fourth to a half a grain of opium; and I find that gr. $\frac{1}{20}$ tartrate of antimony added to this increases the effect. When the rash is gone, I put the patient on protiodide of mercury, and keep him on that, never to the point of salivation, for two years. If he wishes, he is then fit to marry in safety. —*Hearn.*

MEDICO-CHIRURGICAL COLLEGE.

NOT DANGEROUS.

THE accidental escaping of pus into the peritoneum, during an abdominal operation, has little effect upon the subsequent improvement of the patient, if the peritoneum is thoroughly and antiseptically washed afterwards.—*Montgomery.*

ARTHRITIS.

In severe cases of arthritis, where there is a great amount of inflammation, it is good surgery, says Pancoast, to ligate the main artery supplying the joint.

STAPHYLORRAPHY.

The patient, a young man, was operated upon the week before by Stubbs, and the union obtained was most excellent. The after-treatment in these cases is of the most importance; the patient should not be allowed any solid food for some time, and should abstain from talking or anything likely to strain the parts and cause a disunion.

COLLYRIA.

Keyser says that where the mineral astringents are used in eye-washes they should be employed in weaker solutions, and applied more frequently than they usually are.

UNIVERSITY HOSPITAL.

PEPPER presented a man who was suffering with ascites. "There is nothing to indicate peritonitis in his case. On examination I find the edge of the liver thickened and hard, with general enlargement of the whole organ. He has never been a drinker. One gallon of fluid was drawn from his abdomen by the aspirator. His condition is one of hypertrophic cirrhosis with ascites. He will be given a pill of calomel, digitalis, and squills. Will give him at first three grains of iodide of potash and push it to tolerance. We will also apply over the hardened liver:

℞.—Potassii iodidi	gr. xx.
Iodi	ʒj.
Lanolini	ʒj.—M.

His diet will consist of milk, mush, green vegetables, and very little meat. I never despair in the treatment of cirrhosis of the liver."

LUMBAGO.

Mr. S. J., aged forty-six, German, comes to us complaining of a pain in the back. Too often do physicians jump to conclusions, and attribute all pains in the back to rheumatism or a mere sprain. It may come reflexly from hemorrhoids, when it is low down in the back, from an aortic aneurism which presses against the vertebra or nerves, from neuralgia, from a beginning Pott's disease, or various other conditions. Within the last few days a case was referred to me in which a pain near the inferior angle of the scapulæ had been treated as sprain, neuralgia, and other troubles, when in reality I found a condition of caries of the vertebra in that region. This man has been subject to rheumatism, and as we have excluded all other causes we shall diagnose his trouble as rheumatism or lumbago, affecting the structures at the lumbo-sacral articulation. I have never found that you could get good results unless you made an actual application of cautery with the hot iron over the region affected. The cautery will, therefore, be applied over the seat of pain, and he will be placed upon the protracted use of wine of colchicum, ♏ x., with tincture of guaiacum ♏ xx–xxx., three times a day.—*Pepper.*

TYPHOID FEVER.

R. D., aged fifty-six, Irish, brickmaker, admitted nine days ago. Tongue was dry and slightly coated, teeth covered with sordes, much wasted and has lost

about fifty pounds, lungs and heart normal, slight tenderness in the right iliac fossa. Some sudamina on abdomen. Temperature has ranged from 99° to 103°. Dull, indifferent, and has a listless, heavy expression. Tympanites with some diarrhœa. I think this a case of typhoid fever and we shall work on this basis. Give him a liquid diet of mutton-broth and milk; also whiskey ℥ iv every twenty-four hours. Put him on the use of turpentine ♏ v every three hours.—*Pepper.*

CHRONIC MALARIA.

For a person who is saturated with malarial poison Pepper gives:

℞.—Strychninæ sulphatis,
Acidi arseniosi . . . . . āā gr. ¾.
Extracti belladonnæ . . . . . gr. ij.
Quininæ sulphatis,
Pil. ferri carbonatis . . . . . āā gr. xlviij.—M.

Fiat pil. No. xxiv. Sig.—One pill three or four times a day, after meals.

PHILADELPHIA HOSPITAL.

TEETHING.

IN his remarks upon children, Stryker spoke of teething. You will often be consulted by parents in regard to the teeth of their children, and a few remarks on that subject will not be amiss. It is not until after the sixth or seventh month that the teeth begin to give trouble. The central incisors of the lower jaw are the teeth that come first, and the gums become swollen, hot, and uncomfortable, and in such cases cooling and anodyne applications are all that are necessary, for nature usually relieves it. Later on, in cutting the other teeth, the child's rest may be disturbed; sleeplessness and certain constitutional disturbances, as convulsions, or, in hot weather, diarrhœa. In these cases it is well to incise the gum to the crown of the tooth. There is a notion that the scar tissue formed will retard the eruption of the tooth, but it is a fact that scar tissue disintegrates and gives way much easier than normal tissue. It is much better to allow the first teeth to come out themselves, than to pull them, for they act as supports to the second teeth and prevent them from deformed positions. Parents should be instructed to care for their children's first set of teeth, as well as they do the permanent set.

RETENTION OF URINE.

Frequently you will be called in twenty-four or thirty-six hours after birth to see a child that is not able to evacuate the bladder. Examine at once for any malformation—it is always my rule to do this at the time of birth. At birth the prepuce is longer than necessary, but as the child grows older it shrinks. It may be that the opening of the prepuce is pin-like, so that the urine cannot escape. In this case introduce a small probe to break up any adhesions to the glans penis; then introduce a pair of forceps and gradually dilate the foreskin until the glans can be exposed. Do this every morning until the parts are in a normal condition. If these parts are not stretched, there is irritation due to the collected secretion, causing balanitis and constitutional disturbances, such as convulsions and wetting the bed. This simple operation, if done in young children, will save the necessity of a graver operation in after years. Children respond very quickly to these troubles as well as to simple treatment. It is best to tie up the penis in a soft rag saturated with warm water to soothe it, and allow nature to proceed in healing. It may be necessary to apply a little lead-water and laudanum to keep down inflammatory processes.

ERUPTION OF POTASSIUM IODIDE.

I show you this young child, who has an eruption of a papular character, with small, yellow heads, and to all appearances resembles the eruption of measles. It has been taking the iodide of potassium, and now has a typical rash of iodine. This eruption will need no treatment beyond the cessation of the iodine. I wish to impress on you the importance of close inquiry in every case and not jumping at hasty conclusions. One might hastily say yes, baby has the measles, when it is simply the iodide rash.

TONIC.

The following tonic is good for weak stomach and indigestion:

℞.—Quininæ hydrochloratis . . . . . gr. xlviij.
Tr. gentianæ compositæ . . . . . f ℥ iv.
Syrupi zingiberis . . . . . f ℥ ij.—M.
Sig.—Take a dessertspoonful every meal time.

COXALGIA—DEATH FROM ETHER.

D. F., Italian, aged thirty-six; three months ago he was admitted to the hospital suffering from coxalgia; the thigh was slightly flexed, rotated outward and the adhesions prevented extension. On May 4, 1889, he was brought before the class, under the influence of ether, and the adhesions were broken up. He was placed in bed and the limb treated by extension. It grew more painful; an abscess was diagnosed, and, on May 18, he was again brought before the class by Dr. Ransley. An exploratory incision was made over the great trochanter and a large amount of pus escaped. Most of the pus was extra-capsular. The capsular ligament was opened and an examination of the bones did not reveal anything that would justify further operative procedure. The cavity was to be cleansed with bichloride, 1–2000, and absolute rest in bed, with extension, was to be required. The patient bore the ether very badly, and during the latter stages of the operation hypodermics of whisky were freely used; but in spite of this his pulse grew weaker and he was taken from the clinical amphitheater in a dying condition. All means were used to revive him, but death soon ensued. Post-mortem examination showed that the tissues around the joint, as also the psoas sheath, contained pus. He had also manifested symptoms of blood-poisoning previous to the operation. It was noticed that all the organs gave off the odor of ether, and there appears to be little doubt that the immediate cause of his death was the anæsthetic, though the operation was wholly justifiable, as it was his only chance for life.

CHRONIC PARENCHYMATOUS NEPHRITIS.

This case is that of an old woman who has flabby cheeks; puffiness beneath the eyes; a pale waxy look; marked œdema of tissues; pulse slow and of fair tension; urine is amber colored and diminished in amount, acid in reaction; specific gravity 1019; hyaline casts more or less granular; pus corpuscles; epithelial cells, and decided quantity of albumin. In the treatment of these chronic cases, you cannot expect to make a complete cure, for there is a structural lesion of the organ which no manner of treatment can replace. The indication for treatment in this class of kidney trouble is to render the skin active and thus relieve the kidneys. This woman will receive hot-air baths, and if necessary jaborandi. Her diet shall consist exclusively of skim milk. It has been found that, after a prolonged use of skim milk alone, the patient thrived well and every trace of albumin disappeared from the urine; but as soon as this diet was varied albumin returned at once. It is my opinion that the whole milk will answer better, for the fat in it will serve for required nutrition. She will be placed on small doses of carbonate of ammonia for a short time to stimulate her heart; and will also be placed on Basham's mixture.—*Walker.*

TYPHOID FEVER.

In speaking on typhoid fever, Dr. J. C. Wilson claims that 75 per cent. of the cases will get well, with good nursing and suitable diet, without any medicine; 10–15 per cent. will not get well at all, and 10–15 per cent. require medicine. "If there is a specific for typhoid fever, I should say it is carbolic acid and iodine, and I use it in every case of this kind. When the first solid food is given to a typhoid patient during convalescence, a fever may come on (febris carnis) leading one to think seriously of a relapse, but it is of short duration usually. This case is one of a convalescent typhoid, and he is given six grains of quinine and two teaspoonfuls of Basham's mixture."

PROGRESSIVE PERNICIOUS ANÆMIA.

I bring this man before you this morning not to lecture to you upon his condition, but to show you one of the most remarkable results of treatment in the wards of this hospital. Our history on April 2, 1889, shows that he is a Scotchman, aged forty-two years; white; general laborer; has been in America four years; not temperate as regards alcohol; has always been pale; grew weak and had strange noises in his head, accompanied by palpitation of heart; skin had a waxy yellow hue, with slight jaundice; appetite poor, and constipation; systolic blowing at the heart, venous and arterial; bronchitis; spleen almost normal; red blood cells diminished enormously, 600,000 to cubic millimetre; hæmoglobin, 15 per cent.; red cells altered in form and nearly normal in size. May 2, his condition was considered fatal, but the red cells had increased to 1,500,000; hæmoglobin, 30 per cent.; to-day, May 10, red cells number 1,780,000, and jaundice has disappeared, as well as the waxy hue of the skin; his general condition is much improved, and it is my opinion that he will entirely recover. He has not been given iron. He was given Fowler's solution, ♏ iij., three times a day, increased one drop each day, and at present he is taking twenty drops, three times a day. He has also been required to take, at intervals, four or five long, full inhalations of a mixture of two volumes of pure oxygen gas to one volume of nitrous oxide gas, three times each day. The diminished red cells were not able to receive sufficient oxygen from the air to nourish the body, so, by forcing them to use these inhalations, more oxygen was taken up and a consequent improvement from the very first. The arsenic caused some gastric trouble, but was stopped for a few days and again resumed. He has been given the very best diet. This treatment will be continued, and if our patient continues to improve, as he has, he will soon be a well man.—*Wilson.*

HERPES ZOSTER.

This old woman, who was admitted after a debauch, has a rash in the form of a girdle, which extends around her body below the breasts. This is a cutaneous disease associated with neuralgia, and often the pain that precedes the appearance of the rash is very severe for some time. This woman developed an acute intercostal and infra-orbital pain of a burning character, following which was a crop of vesicles from a pin-head size to that of a split pea, having their long axis with the axis of the intercostal and infra-orbital nerves. Treatment consists of small doses of morphine, repeated simply to control the pain. Moderate doses, gr. v., of antipyrin will often control the neuralgia. Large doses of quinine also relieve neuralgia, but are unsatisfactory. The simpler the local treatment the better. Nothing is gained by poultices. Prevent irritation from clothing by a flannel bandage. Powders are useless, except when the vesicles burst. Ointments are disagreeable and not much good My own feeling is that the application of collodion, somewhat diluted with ether, and to which is added morphine gr. j to ʒj, is all that is required. Collodion covers the rash with a thin film that excludes air and irritation from clothing. After using a good many forms of treatment, I find antipyrin, morphine, and collodion give the best results. Duration is from ten days to two weeks, healing with slight scars on the face. It is a disease to which certain families show a predisposition.—*Wilson.*

HOW TO OPEN AN ABSCESS.

Ransley says that abscesses in the deep parts of the side of the neck should be opened thus: make an incision through the skin with your scalpel, introduce your grooved director into the abscess, and with a pair of forceps dilate the opening sufficiently to allow a free escape of pus. Wash the cavity with bichloride 1–2000, and dress antiseptically. Although this is rather a rough manner in which to evacuate an abscess, yet you are not liable to injure any of the important vessels or nerves that might otherwise be severed by a knife.

DR. EDSON gives a timely warning against typhoid fever, and ventures the broad assertion that there is probably not a well in the country whose water is fit to drink.

ASYLUM INVESTIGATIONS.

WE look upon these investigations of insane asylums as an unmixed benefit to those institutions. Not that they often succeed in unearthing veritable abuses, even when they really exist, but they serve to bring back the attention of the hospital attendants to the fact that their duties are not those of turnkeys, but of nurses. It must not be forgotten that these duties are singularly difficult. Lunatics are not easy to manage. They are sometimes irrational, swayed by insane impulses, evil in thought, treacherous, lying, quarrelsome; in a word, they possess sometimes the ingenuity of fiends in making themselves disagreeable. It is necessary for their own good that they shall be held in subjection, and not suffered to injure themselves or others, or to destroy property wilfully. As the object of their treatment is to restore their power of self-control, discipline is a primary means of cure.

When the officers of an asylum are capable, when they are endowed with the necessary mental qualifications to secure the respect of their charges, when to the knowledge of the medical art and mental philosophy, they add an earnest desire to benefit their patients and a ready sympathy for their infirmities, the task of controlling the insane is not difficult. For there are few insane persons who will not recognize the presence of a warm, sympathetic heart, and give their assistance to an earnest effort to do them good. When this spirit animates the whole institution from the superintendent down, there is little to fear and much to gain from public investigations.

But if the attention of the officers be engrossed with any interest other than the individual welfare of the inmates, it is different. The attendants soon perceive that the first duty demanded of them is to keep the patients from annoying their superiors, and that as long as this is done, the latter are indisposed to look too closely into the methods employed to bring about the desired result. This is so true that even attendance at professional assemblages, and the preparation of papers to be read at them, is held to detract from the more essential ward-work of the asylum physician. When this condition exists, abuses are sure to creep in; abuses which cannot be brought out by an investigation. A black eye or a broken bone can be blamed on another patient; as the inmates are just as likely to be cruel to each other as the attendants. The testimony of patients is a very uncertain guide, except to those who are familiar with them. For these reasons, abuses may exist which jeopardize the lives and prevent the restoration to reason of the patients, and the asylum officials be ignorant of it. The hospital becomes in effect a prison; where order and discipline, safe-keeping and feeding, with such treatment as will prevent the annoyance of others, are the only objects aimed at. When patients recover their reason, it is more by the grace of God than by the intelligent application of the art of the alienist.

Practically, this is not often the case. Those who are at the head of our asylums are almost invariably men of the highest mental and moral qualifications, who devote their lives to the study of their patients, and who know them too intimately to be deceived by an attendant's stories. By unwearied diligence they make up for the difficulties under which most of them labor from the want of intelligent attendants; and real cases of cruelty are very rare in the institutions controlled by these men.

Hence, as we have stated, we look upon these investigations as highly beneficial; as bringing back those who are in authority over lunatics to a sense of the demands of humanity, and directing their attention forcibly in the line of their most important duty.

There is another aspect of this case, and it is surprising that it has never occurred to the sharp-sighted members of the press. In their investigations of the inner workings of the asylum, they do not seem to have been struck with the exceptional qualifications demanded for a good attendant, and the impossibility of procuring such persons for the low wages now paid. The man or woman who has enough tact to keep in order a ward full of lunatics without resorting to force, is expected to work for the wages of an ordinary house servant. Problems which would test the skill of an Esquirol are left to nurses who can hardly read and write. The true moral of these scandals is simply this: exercise the greatest care in the selection of the staff of an asylum, and then pay the members enough to warrant them in devoting their lives to the work.

WE are pleased to announce that the celebrated clinician, Dr. Dujardin-Beaumetz, has joined our editorial corps, the American Medical Press Association.

DR. BIGGS has testified that he has discovered evidences of hemorrhage at the base of Bishop's brain, sufficient to cause death. Let us hope that this question is now definitely settled; and in a way to put at rest all the gruesome suspicions which have been circulated.

Annotations.

JOHNSTOWN.

A RUSH of flooding waters, and the terror of death suddenly falling upon thousands, and a city of forty thousand inhabitants is blotted out of existence. The greatest calamity of modern times has fallen upon the valley of the Conemaugh, and out of the string of towns along her banks many thousands lie dead; overwhelmed in the flood, crushed among the wreckage of falling cities, or, worse yet, roasted in the flames which broke out in the chaotic mass of houses packed against the bridge.

A leading characteristic of the age is the security afforded to life and property; which, imperfect as it may appear to us, has steadily increased since the Middle Ages. The rule of law and the science of the engineer have combined to make the horrors which mainly form what we term history, comparatively infrequent in modern times. This renders still greater the shock when such an appalling catastrophe occurs as that of Johnstown.

It is certain that there will be great distress among the survivors; and that the contributions which are pouring in from every quarter will all be needed before the district will again become self-supporting. Our own profession is among the first to respond; and a number of physicians have left Philadelphia for the recent disaster. What with grief or despair, added to the effects of bodily injury and exposure, their services will be badly needed.

The improvised hospitals in the neighborhood are crowded to overflowing, while all sorts of temporary shelters are being utilized. Our city hospitals will probably be called upon to accommodate some of the sufferers who can be moved, and active preparations are being made to receive them. Jefferson has sent a corps of surgeons to the front, under the competent leadership of Prof. Forbes, with an ample store of surgical dressings.

The Medico-Chirurgical Hospital has placed her fifty beds at the disposal of the authorities, making provision elsewhere for her present inmates.

Prof. Pancoast has got the Red Cross Association actively at work, and has sent a contingent of surgeons to the front. The University has also supplied a number of workers. Prof. Keen has called an extra meeting of the County Medical Society, and has authoried a draft upon its treasurer for $500. It is probable that the meeting of the State Medical Society at Pittsburgh has been seriously marred by this calamity; many physicians turning aside to go to Johnstown, and others being detained on the way by the widespread injury to the railroads caused by the floods.

THE *Journal of the American Medical Association* comes out on May 25, with an edition of 75,000 copies. The Journal gives evidence of careful and competent editorial supervision; and if it is now under a temporary management, the Association can scarcely do better than make the present arrangements permanent.

THE ELEVENTH CENSUS.

IN another column will be found an official circular from the Superintendent of the Census requesting physicians to aid in the work of collecting statistics, and announcing that the eminent statistician, John S. Billings, has consented to take charge of the Report on Mortality and Vital Statistics. Dr. Billings has been before the medical world so long that any reference to his great abilities is superfluous. As a statistician he has succeeded in investing his rather arid subject with an interest previously unknown. Most of our readers will remember the sensation with which his famous malarial map was received by the medical profession; a work upon which undoubtedly depends the degree of popularity which he enjoys in the West and South. His broad manner of dealing with his subject, taking in whole empires at a single sweep, regardless alike of minor considerations, such as individuals and facts, his freedom from anything like personal bias in the exercise of official authority, all combine to increase the interest excited by the announcement, that this brilliant imagination is to have a new and wider field in the manipulation of the vital statistics of the Eleventh Census of the United States.

We hope that in one respect this Census will be an improvement upon the last, in that the promises made to physicians will be kept. It will be recollected that copies of the portion of the Census of special interest to the medical profession were promised to those who contributed to these statistics. We have been unable to find any one who has received the promised copy.

IN the *Journal of the American Medical Association* for May 25, 1889, is an interesting table of information concerning the medical colleges of the United States and Canada. In it we note with surprise that the Pennsylvania medical colleges are credited with the command of beds for clinical instruction as follows: Western Pennsylvania Medical College, 200; Medico-Chirurgical, 50; Women's, none; Jefferson, 150; University of Pennsylvania, 1100! It will be news to many that the University Hospital has 1100 beds, unless this includes the Almshouse.

DR. GIHON has been laboring for years to have a monument erected to Dr. Benjamin Rush. If one alone out of America's bright galaxy of physicians is to be thus honored, there is none on whom the profession can more readily unite than on Dr. Rush. But little would be needed if each were to do his part. Let each of our readers who goes to Newport take with him a little offering for this good cause, and let those who disappoint their brethren by staying at home send a double portion.

THERE are vacancies in four vaccine districts in Philadelphia. These are to be filled by competitive examination, the "civil service rules" in this case being really intended to afford some grounds for judging of the merits of the applicants.

Society Notes.

OHIO STATE MEDICAL SOCIETY.

THIS Society met in its forty-ninth Annual Session, at Youngstown, May 22, with the President Dr. P. S. Connor, of Cincinnati, in the chair.

LARYNGEAL PHTHISIS

was the subject of a paper read by Dr. A. B. Thrasher, of Cincinnati. He said it is established beyond a reasonable doubt, that at times this is a primary affection. While the rule remains that the lungs are generally affected either with or before the larynx, yet Demme's case has disproved the statistics of Heinze, as tubercular disease of the larynx was found in death from tubercular meningitis. The special reason for invasion of the larynx was thought to be due to a weakened condition of the organ from abuse of the voice: either by improper method, over use, or by using the voice in a bad atmosphere. The theory of specific infection by the Koch bacillus would scarcely hold good, as if the bacilli were inhaled the nasal mucous membrane should be more frequently affected. If it were exhaled from the lungs or carried out in the sputa, the surface of the mucosa would be first affected, while, as a matter of fact, the tubercular disease first began below the surface.

In uncomplicated cases, Dr. Thrasher thought the laryngoscopic examination would establish the diagnosis. Small, multiple ulcers with ragged edges on the under surface of epiglottis, the edges of the vocal bands or over the aryepiglottic folds, on a pale, œdematous surface, would mean tubercle. Pale thickening of the free edge of the vocal band or of the tissue over the arytenoids, this latter assuming a pyriform shape, implies tubercle. In syphilis, the ulceration is on the buccal surface of epiglottis, but one large ulcer surrounded by highly inflamed tissue with involvement of cervical glands. In cancer, one ulcer on the apex of a tumor usually on the ventricular band, preferably the left one, with marked redness of larynx and pharynx.

The general treatment does not differ from that of phthisis pulmonum. Locally, lactic, chromic or acetic acid to the ulcers: or, preferably, the galvanic cautery. Cocaine, menthol, morphine, by spraying solution in vaseline during inhalation. By these means the patient is able to take food and is free from much excruciating pain which accompanies the last stages of laryngeal phthisis.

Dr. Max Thorner, of Cincinnati, read a paper on

CHRONIC PAINFUL AFFECTIONS OF THE THROAT.

Pharyngitis as well as laryngitis, is sometimes due to rheumatism. These cases are usually very obstinate and resist every treatment, except that which is directed against the diathesis. The symptoms are, pain in or about the throat: in pharyngeal affections the pain is mostly located in the regions of the fauces and tonsils, and sometimes as far down as the hyoid bone. If the larynx is concerned, there is localized pain in and around the larynx, the whole region about the larynx and the upper part of the trachea may be painful to pressure: some tender spots are always present. The pain is intermittent and patients suffer more during changeable weather. Locally, there is more or less congestion, which is sometimes circumscribed and limited to small tender spots. In rare cases, congestion may be absent. Neither ulceration nor swelling are found in the throat. The general health of the patients remains undisturbed, unless they suffer at the same time from other manifestations of rheumatism.

The diagnosis must be based on the history of the patient. Sometimes rheumatic sore throat is found in people who have never suffered from rheumatism, but in the majority of cases this disease can be traced among their former ailments. The treatment for this affection must be chiefly that for rheumatism in general: local applications may assist in the treatment, but can never alone effect a cure. Salicylate of soda, salol, oil of wintergreen, phytolacca and iodide of potassium, are of special value. Sometimes hot applications, the faradic or galvanic current, are very effective in producing relief. One case, a lady of pronounced rheumatic diathesis, was not amenable to treatment until she had spent several weeks at the hot springs in Mt. Clemens, Mich., whence she returned cured. Chronic rheumatic affections of the throat are found more frequently in men than women. Relapses are common.

Dr. J. C. Reeve, of Dayton, presented a paper on

THE EARLY DIAGNOSIS OF EXTRA-UTERINE PREGNANCY.

It was based upon a careful study and annotation of the symptoms present in a large number of reported cases, and was prepared with the object of directing the attention of general practitioners, into whose hands the majority of these cases fall, in order that relief may be afforded in time. The symptoms were individually considered and classified as: 1. Suggestive. 2. Presumptive. 3. Certain. By an attentive study of these, a diagnosis could generally be made, although in some cases the difficulties were insuperable. The subject of treatment was only considered to show how the advocacy of different methods had led to undue depreciation of the possibilities of a diagnosis at an early period.

Secretary Collamore's report showed a membership of five hundred and seventy-eight and a decrease of eleven county societies in the State.

On recommendation of the Finance Committee the dues were made $2.00, and the salaries of the secretary and treasurer were increased from $75, to $125 per annum.

Election of officers resulted as follows: President, Dr. John McCurdy, of Youngstown; First Vice-President, Dr. W. J. Conklin, of Dayton; Second Vice-President, Dr. A. W. Ridenour, Massillon; Third Vice-President, Dr. C. W. Tangeman, Cincinnati; Fourth Vice-President, Dr. J. E. Woodbridge, Youngstown; Secretary, Dr. G. A. Collamore, of Toledo; Assistant-Secretary, Dr. E. C. Brush, of Zanesville; Treasurer and Librarian, Dr. T. W. Jones, of Columbus. Columbus was chosen as the next place of meeting the first Wednesday in June, 1890.

CINCINNATI MEDICAL SOCIETY.

A CASE of Œdema of the Larynx which produced much discussion was reported by Dr. A. D. Birchard. What seemed an ordinary cold in a young man of nineteen, developed in twenty-four hours into an aggravated croupous condition with alarming dyspnœa. The speaker was then sent for and found intubation necessary. Three attempts were made to insert a tube, but the patient expelled each by coughing. The man was almost asphyxiated when all was ready for tracheotomy, which was successfully performed, the temperature never being over 102°, and normal the fourth day. The tube was removed then as phonation was restored, but the respiration became so embarrassed it was necessary to replace the tube. The after-treatment consisted in keeping the atmosphere saturated with moisture. The tube was finally removed the eighth day, and the patient put upon tincture of iron. His improvement was quite rapid, and in two weeks he resumed work.

Dr. B. P. Goode, who assisted in the operation, thought the case very much like the one from which Washington died, as now understood. In this instance there was some thickening of the epiglottis and parts about it.

Dr. Thorner said there is but one thing to be done in these sudden cases of acute œdema of the larynx, viz., tracheotomy. He related two cases of his own, in which scarification and the hypodermic use of pilocarpine relieved the impending suffocation. The tubes with the intubation case are not long enough in most instances. If the tube is long enough to protrude from the mouth, he thought it would be of service in œdema of the glottis where the usual tubes are of no benefit.

Dr. R. B. Hall reported the history of a case of Gunshot Wound of the Abdomen. Senn's test for perforation of the intestines by means of hydrogen gas was attempted, but was unavailable; the post mortem revealed that the long track of the bullet had filled the tissues with blood clots, hence the impossibility of introducing a probe or canula to let out the gas.

At a recent meeting Dr. C. P. Judkins discussed the connection of Chronic Eruptions and Internal Diseases. He reported the case of a gentleman who suffered from an eczematous eruption of the hands and arms. A stay at Hot Springs failed to remove it, but three days before he had an attack of pneumonia the eruption disappeared, but on his recovery it reappeared.

A successful case of Induction of Premature Labor in contracted pelvis was reported by Dr. W. H. Taylor. The means of inducing labor was the flexible bougie, which proved so satisfactory in his hands that he thought no other means necessary of consideration. After the labor has commenced, if the woman is in a good condition, he thought she should be let alone for a time. Generally, indications for artificial delivery will arise, and then the question of forceps versus version presents itself for consideration. Dr. Taylor thought that if the head had entered the brim and then ceased to progress, forceps were clearly indicated, and especially the axis traction forceps. If the head remains movable above the brim, after fair efforts at expulsion have been made by the uterus, the use of the forceps will probably result in harm to the mother and child, and it is better to resort to version. He did not advise, as a rule, the application of the forceps to the after-coming head, but said there were cases in which it is indicated. The determination of the exact character of the deformity, and the character, and size, and age of the fetus he considered matters of the greatest importance. In the case reported both mother and child were saved. The child was at the eighth month and was kept in Tarnier's couveuse.

The Inquirer.

G. W. C.'S CASE.

"G. W. C." wants some suggestions about the case of Mrs. H (The Times and Register, May 18, p. 66). I had a similar case some three years ago. Mr. P., a man about forty-five years old, who had always enjoyed good health, came to me complaining of intense thirst; he was passing a large quantity of urine, between three and four gallons in twenty-four hours. As there was no trace of sugar in the urine, I called it diabetes insipidus.

I gave him ergot and other remedies recommended for that disease, but without benefiting him. I decided to try the effect of turpentine, giving doses of fifteen to twenty drops, three times a day. He soon began to improve under this, and in four weeks was cured. He has had no return of the trouble up to the time of writing. Try the remedy and report results.

A. Libby, M.D.

Richmond, Me.

IS ANTIFEBRIN DANGEROUS?

VARIOUS authorities agree in pronouncing antifebrin a safe and reliable antipyretic, useful in quickly reducing temperature without any untoward results. Yet my experience does not justify me in coinciding with my cotemporaries, as results will show. Having had personally but limited experience with the drug, I concluded recently to test its properties in a case of infantile fever by administering a four-grain dose to a child of three years of age, whose temperature persistently remained at from 101° to 103°. Hardly had one-half hour elapsed when I was summoned to the bedside to find that the dose had done its work effectually, as temperature was below normal, with impending collapse indicated by cold extremities, feeble respiration and labored heart's action. Prompt administration of restoratives prevented the impending result and the patient was eventually restored to health; but under other treatment than that afforded by antifebrin. As no organic heart derangements existed and the drug was supposed to be a prime article, we are at a loss to account for its peculiar action in this instance, unless some idiosyncrasy of the patient existed, or the much vaunted antipyretic properties of the drug are of a dangerous

character. If so, it should be administered with circumspection.

A. L. SAYLOR, M.D.,
Surgeon-General Oregon National Guard.
NORTH POWDER, OREGON.

INFLAMMATORY SWELLING OF BOTH GREAT TOES IN A CASE OF FEVER.

I WAS called, on April 14, in consultation, to the case of a young man who had been sick one week. The range of temperature had not been high, was now 100°, pulse weak and frequent; tongue dry, brown, furred, red edges; skin dry; urine quite scanty; bowels slightly constipated; there was a yellowish tinge of the conjunctivæ. For three days there had been progressing an inflammation, considerable swelling, and intense pain of both great toes; serum forming under the skin; they looked as if they might soon become gangrenous.

This was, to me, the most remarkable feature of the case, and it is for the purpose of eliciting the views of yourself, or any of your readers, in regard to the nature of the case, and the relation of the toe trouble thereto, that I request your consideration of the case.

Taking a general view of the symptoms, they correspond, at the same time, to those cases of continued malarial fever as seen in the south-west.

Another thing noted at the examination was the pain produced in lumbar region by abdominal palpation; there was also some pain in lumbar region independent of palpation, which was attributed to renal congestion.

However, there being pain also in the left gluteal region, much increased by even gentle pressure. I said to the doctor, that while we could only diagnose continued malarial fever, I felt strong suspicion of abscess, and to look out for further developments.

Afterwards, I learned that the swelling of toes soon subsided, and that about the fourth or fifth week an abscess opened in the gluteal region and discharged a large quantity of fetid pus. About ten days later another opened in the lumbar region and discharged freely.

When I last heard from patient abscesses were still discharging and he wearing out.

Please let us hear, through THE TIMES AND REGISTER, from any one who can give information on the case, and *especially in regard to the affection of the toes.*

The physician in charge of the case had diagnosed "spotted fever," and declares that he had seen such an affection of the toes in several cases of "spotted fever." No other cases of the disease had appeared.

During an epidemic of cerebro-spinal meningitis, some years ago, I heard authentically of a boy who was seized with intense pain in the great toe, which continued from the first moment of his illness until death occurred in about forty-eight hours.

A. A. DUNN, M.D.
PURCELL, IND.

[If the inflammation of the toes preceded the suppuration in the gluteal and lumbar regions, the latter were secondary abscesses, due to the migration of pyogenic bacteria along the lymphatics. We have seen a suppuration in one great toe give rise to abscesses in the corresponding calf and in the thigh below the crural opening. As to the cause of a simultaneous suppuration in both great toes, we can only conjecture. It is, of course, a curious coincidence, unless there were some special exposure of the feet to septic matter, but of this the history gives us no account. If the patient had been cleaning a privy well or a drain, with leaky boots on, or spreading putrid manure, the coincidence would not be so remarkable. There is nothing to indicate any continued fever, unless the physicians of that locality have learned to associate such attacks with malaria, etc. W. F. W.]

Book Reviews.

PROCEEDINGS OF THE SOCIETY FOR THE STUDY OF INEBRIETY. No. 20, May, 1889. Published for the Society by H. K. LEWIS, 136 Gower Street, W. C. Price, sixpence.

This number is notable for giving an explanation of the report upon which was based the absurd statement that teetotalers do not live as long as habitual drunkards.

THE EAR. By C. H. BURNETT, A.M, M.D. Philadelphia: J. B. Lippincott Company, 1889.

This little book is one of a series of lessons on practical nursing, issued by this well-known publishing house. It is a well-written and instructive book for the people. It is not intended for the student or physician, but for family use. It gives instruction on what to do in diseases and injuries of the ear, and what is especially good is the advice for the prevention of these troubles, while it does not interfere with the attention and duties of the physician. The author is so well known as an accomplished specialist on the ear that anything he may write cannot but be received as authority in this branch of medical science.

A TEXT-BOOK OF PATHOLOGY, SYSTEMATIC AND PRACTICAL. By D. J. HAMILTON, M.B., F.R.C.E., F.R.S.E., Professor of Pathological Anatomy, University of Aberdeen. Vol. I. London and New York: Macmillan & Co., 1889. Pp. 736. Price, $6.25.

Prof. Hamilton in his preface justly takes a broad view of the scope which he considers a work on pathology ought to cover, saying: "It will, I think, be granted that the pathology of to-day is not delimitable merely as a matter of pure morbid anatomy, pathological histology, pathological physiology, pathological chemistry, or clinical medicine, but that these are simply members of a great body, and that they are indissolubly bound together."

We are also pleased to see that the author acknowledges the importance of clinical experience as a kind of inhibitory power. Many of those whose life is spent chiefly in the laboratory among phials, chemicals, exact instruments, and "scopes" of all kinds, are apt to reach conclusions and to issue arbitrary statements widely at variance with those phenomena which the clinician knows to be facts, not mere inductions or deductions from assumptions.

Prof. Hamilton says: "In order to arrive at a solution of the great problems of disease, many accessory means of investigation must be adopted. Experiment must be largely resorted to, exact methods of physical research must be drawn upon, animal chemistry must be called in to assist, comparative pathology must contribute largely, and, lastly, the whole record must be controlled by the results of clinical observation."

Part I is practical. The author gives minute directions for making post-mortem examinations, describing the necessary instruments, and then the proper method to pursue in examining each separate organ, closing with a form for an ordinary, and also for a medico-legal, report.

In a medico-legal case, he advises that both the heart and the brain be exposed before either is opened, so that they may be examined in their normal relation, and thus no question be raised as to their actual condition before being disconnected.

We agree with Prof. Hamilton that but little satisfaction can be gained from examining a fresh brain, and that the investigator will be richly repaid for waiting the necessary five or six weeks till the brain has hardened.

Chapters IV, V, and VI give full directions for making museum preparations, hardening tissues, cutting, mounting, and staining sections, along with a large number of formulas for staining and hardening fluids.

The microscope is not forgotten, but, as is proper in a text-book, directions are given for choosing an instrument and for handling it.

Practical Bacteriology receives forty-five pages, devoted to culture media, sterilizing processes, staining, and the like.

In the second part General Pathological Processes are considered. We must here take exception to the author's definition of health: "Health is that condition of structure and function of an organism which, on examination of a sufficient number of examples, we find to be the commonest." This will not answer. Ophthalmologists tell us, for instance, that an absolutely emmetropic eye is not to be found, but that more or less defect, myopia, hypermetropia, or astigmatism is always present. Probably most eyes are myopic, yet who considers a myopic eye as healthy?

In this part the author takes up the various infiltrations and degenerations, inflammation, suppuration, organization, ulceration, and dropsy.

The chapters on inflammation are especially worth reading, the classical experiments in relation to this important topic are cited, along with many new ones by the author.

In the third part the author begins to consider separately the Diseases of the Various Organs and Tissues. The different tumors, epiblastic, mesoblastic, and hypoblastic are first discussed, then the blood, and finally the heart and the bloodvessels. This is as far as the first volume extends. Every part of the work is copiously illustrated, there being in the present volume seven hundred and twelve engravings. Unfortunately, however, these are not of a particularly high grade of execution, and, indeed, the lithographs are actually poor. In their favor, though, it may be said that they are mostly new, by the author's own hand, and are thus agreeable, because they are not the time-honored, well-known drawings that greet one's eyes in book after book. The style in which the matter is printed is to be commended. Each new subject has an appropriate heading in capitals, and all important words in the context are distinguished by special type. The book is thus rendered much more agreeable to the eye and readable than it would otherwise be, and this is a point which we think is, as a rule, more often recognized by American than by foreign authors.

Prof. Hamilton's bibliography is most complete and excellent, showing a large amount of work. Taking it all together, the author has contributed a work of much interest and value on the vast and fascinating subject of pathology.

ALCOHOL INSIDE OUT; from Bottom Principles. Facts for the Millions. By ELISHA CHENERY, M.D., Boston. Philadelphia: Records, McMullin & Co., Limited, 1889, pp. 340. Price, $1.50.

In view of the present prohibition excitement this little work may be called a timely one. Dr. Chenery must have devoted much time and labor to the collection of hundreds of different statements by various writers, more or less well known, all tending to prove that alcohol is an unmitigated and unnecessary evil. Dr. Chenery himself, besides his citations, treats the subject most thoroughly from every point of view—chemical to moral—and certainly makes a strong plea in favor of total abstinence.

ATLAS OF VENEREAL AND SKIN DISEASES. With Original Text. By PRINCE A. MORROW, M.D. New York: William Wood & Co., 1889.

Fasciculus XIII.

Plate LXI, Elephantiasis of Leg and of Scrotum (after Araujo).

Plate LXII, Leucoderma (after Neumann); Alopecia Areta (author's collection).

Plate LXIII, Keloid (after Hyde); Fibroma (after Ouchterlony).

Plate LXIV, Xanthelasma (after Hutchinson); Rhinoscleroma (after Neumann).

Plate LXV, Xeroderma Pigmentosum (after Vidal).

The illustration of leucoderma fails to show the thickening of the pigment at the margins of the white spots and the shading off into the surrounding skin, which is characteristic. That of keloid is not a very good specimen of the disease; not nearly so good as one shown by Maury many years ago, and repeatedly figured since.

In both cases the deficiencies are fully compensated by the accompanying text. Upon this we have no criticism save that we think Dr. Morrow should have insisted upon the necessity of separating children with alopecia from their companions, especially in the schools. This has been urged by the Paris Academy, and is all the more important, as without such caution physicians are apt to overlook the precaution.

ARE VENOMOUS SNAKES AUTO-TOXIC? By Surgeon L. A. WADDELL, M.D., Deputy Sanitary Commissioner, Bengal. Calcutta: Government Printing Office, 1889.

To obviate all sources of error in the experiments made with the view of answering the above question, Dr. Waddell obtained freshly caught, uninjured snakes, and injected the venom hypodermically. The result of his investigations is to show that serpents are not injured by their own venom; that other venomous serpents are in some cases poisoned, in others not, and that harmless snakes are generally killed by the venom of their poisonous relatives. He believes that the immunity of snakes against their own venom is acquired by inoculation with small quantities through abrasions in the mouth.

EXTRA-UTERINE PREGNANCY. A Discussion. From the Transactions of the American Association of Obstetricians and Gynecologists, 1888. Together with an Editorial Review of Tait's "Ectopic Pregnancy and Pelvic Hæmatocele, from the Buffalo *Medical and Surgical Journal*. Philadelphia: Wm. J. Dornan, 1889. Price, 75 cents.

The need of a more accurate knowledge of such an important subject as ectopic gestation with all of its attendant evils, and especially of the means of diagnosticating its presence during the early weeks of pregnancy, cannot but impress itself upon the serious obstetrician. The almost certainty of an early fatal termination, or of a prolonged and tedious invalidism should the primary rupture assume its most favorable aspect, demands that the most earnest investigation should be instituted of an accident, which, though fortunately rare, is yet, as we are led to believe by recent reports of post-mortem examinations, of more frequent occurrence than we have hitherto conjectured. It is with this purpose in view that this little volume is presented to the profession, containing as it does a discussion before the American Association of Obstetricians and Gynecologists, participated in by some of the leading specialists in the country. The causes, pathology diagnosis, and treatment of the condition, are thoughtfully considered, and while there is still considerable controversy as to the mode of treatment which should be adopted, the weight of opinion seems to tend away from electricity and toward the stand taken by Tait for operative procedures. Condensed into a small space, the whole subject of extra-uterine pregnancy is placed before the profession in a most concise and acceptable form.

EXECUTION BY ELECTRICITY.—*American Notes and Queries* has instituted an inquiry among the most eminent scholars of the country to determine the best word to express execution by electricity. The answers as far as received are remarkable for the variety of suggestions. Among them are electrophon, electricize, electrotony, electrophony, thanelectrize, thanatelectrize, thanatelectrisis, electromort, electroctony, electroctasy, fulmen, electricide, electropœnize, electrothenese, electrocution, electroed, electrostrike, and, finally, joltacuss or voltacuss. The last is the suggestion of Bill Nye.

Pamphlets.

Fourth Annual Announcement of School of Dentistry, of Meharry Medical Department of Central Tennessee College, 1888–89.

Some Principles governing the Preparation of Food for the Sick. By Frederick P. Henry, M.D., Philadelphia.

This is an interesting and instructive lecture that was delivered to the Training School for Nurses at the Episcopal Hospital Philadelphia.

Food Versus Bacilli in Consumption. An open Letter from Ephraim Cutter, M.D., LL.D.

The Question of Relationship Between Lichen Planus (Wilson) and Lichen Ruber (Hebra). By A. R. Robinson, M.B., M.R.C.P., New York. In this able and exhaustive paper illustrated with a number of microscopical drawings and microscopical colored plates, the author concludes that there is no relationship between the two diseases.

On the Nature and Treatment of Epistaxis. By Alexander Harkin, M.D., F.R.C.S., Belfast.

Thirty-sixth Annual Report of the Pennsylvania Training School for Feeble-minded Children, Elwyn, Pa.

This is one of the most commendable institutions that we know of and worthy of all support.

On Some Mild Measures in the Treatment of Intra-Nasal Hypertrophies and Inflammations. By W. H. Daly, M.D., Pittsburgh, Pa.

On the Relation of the Nasal and the Neurotic Factors in Ætiology of Asthma. By F. H. Bosworth, E. L. Shurly, W. H. Daly, and Andrew H. Smith.

Station-List of officers of the Medical Department and Hospital Stewards of the Hospital Corps, United States Army. March 1, 1889.

Report of Forty-eight cases of Alexander's operation. By J. H. Kellogg, M.D., Battle Creek, Mich.

Fourteenth Report of the Board of Managers of the Hospital of the University of Pennsylvania, year 1888.

Fourteenth Annual Announcement of Meharry Medical Department, of Central Tennessee College, Nashville Tenn. 1888-9.

Thirty-Fifth Annual Report of the Board of Managers of the Howard Hospital and Home for Incurables, Philadelphia.

Stomach-washing in Infants. By A. Seibert, M.D., New York.

A New Procedure in Cases of Anticipated Complete Rupture of the Perineum. By Edward B. Weston, A.M., M.D., Chicago.

The Annual Report of Department for the Insane of the Pennsylvania Hospital, 1888.

Alcoholism and Pulmonary Consumption. By Thomas J. Mays, M.D., Philadelphia.

Lacerated Cervix Uteri as Treated at the University Hospital, by Prof. William Goodell. By Lewis H. Adler, Jr., M.D., Resident Physician, University Hospital, Philadelphia. Reprint from *The New York Medical Journal* for March 2, 1889, 9 pages.

Simply a review of the recognized plan of procedure in operations upon the cervix for laceration. A brief summary of the results which may follow non-attention to the condition is presented.

Non-closure of the Abdomen. By Wm. P. Hogue, M.D., Charleston, W. V. Read before the State Medical Society of West Virginia, Twentieth Annual Session, July 13, 14, and 15, 1887, 5 pages.

The freaks of nature are alike interesting and varied in their expression and admittance of surgical interference. Dr. Hogue's case is especially remarkable for its favorable termination.

Foreign Body in the Peritoneal Cavity. By J. L. Crawford, M.D., President of the Westmoreland Co. Med. Soc., Greensburg, Pa. Reprint from *Medical and Surgical Reporter*, Dec. 15, 1888.

A very interesting report showing the remarkable degree of tolerance exhibited at times by the delicate peritoneal membrane.

Gleanings.

AURAL POLYPI.—Pratolongo makes use of the following :

℞.—Acidi acetici . . . . . gtt. xv.
Acidi chromici . . . . . gtt. iij.—M.

Three drops of this are injected into the polyp, which contracts and becomes yellowish, and drops off on the third or fourth day.

TREATMENT OF SCROFULOUS GLANDS.—Treves (*British Medical Journal*) holds that the cheesy mass in a caseated gland is in no way a deposit; it represents the débris of a chronic inflammation. It is entirely non-vascular, and can undergo no organic change. It is as much a foreign substance as a sequestrum, and in due time will excite suppuration around it and be discharged. Under no circumstances can the caseous mass itself break down into pus. He objects to any treatment except excision.

Buzzard believes that scrofulous glands are less commonly seen than formerly, because the milk supply is better.

LACTEAL SECRETION DURING AN IMAGINARY PREGNANCY.—Dr. Demange reports a case of a married woman, æt. twenty-eight years, of a nervous temperament and extremely desirous of becoming a mother, who consulted him on several occasions, imagining herself to be pregnant. On examination, however, this was proved to be erroneous, but he could not succeed in so convincing the patient. At about the fifth month of her pretended pregnancy she returned triumphantly, announcing the presence of milk in her breasts, and to his astonishment he found that by pressure he could produce from the nipples several drops of a fluid analogous to colostrum. This rudimentary lactation was accompanied by a notable increase of size of the breasts, but there was no increase of pigmentation nor even the tubercles of Montgomery in any way developed. Twelve months later the patient gave birth to a child which she nourished herself.—*Archives de Tocologie.*

LAPAROTOMY FOR PUERPERAL PERITONITIS.—L. H. Evans, M.D. (*Med. Press* of Western New York), was called to see a patient who, one week previviously, had miscarried at three months; temperature, subnormal; pulse, 157; respiration, 34. The woman was covered with clammy sweat, and appeared to be moribund. Consultants agreed as to her danger, and that the only chance was to wash out the abdomen. After opening the abdomen, the patient was turned over and a quart of serum allowed to drain away. The cavity was now filled with warm water, which was emptied out in the same manner as the serum. The patient did well till the third day, when a severe chill warned the surgeon of the presence of pus. He once more opened the abdomen, found a pint of pus, washed out the cavity again, closed it, and from that time the woman made a good recovery.

EXCISION OF THE CÆCUM.—Durante, at the Bologna Surgical Congress, reported the case of a woman who had a tumor in the cæcum, of four or five years' standing. She had great pain on defecation. The abdomen was opened, and a tumor the size of a lemon was found in the iliac fossa, adherent to the peritoneum and with the small intestines firmly matted with it, so that a portion had to be removed with the tumor. The severed bowel was united by three rows of sutures; interrupted through the mucous coat; hemstitch through the serous and muscular and a third through the serous. The patient made a rapid recovery; the tumor was tuberculous.—*British Medical Journal.*

EXPERT TESTIMONY.—Samuel Ward, M.D. (*The Sanitarian*) contributes an able article on medical expert testimony. He cites what are known to be facts, namely, that the whole proceedings in obtaining expert testimony are frequently a mere farce, an exhibition of legal jugglery on part of the opposing counsel; that the so-called "expert" testimony is often of the most insane character, because the badgering and brow-beating of the hostile attorney has hopelessly confused the medical man.

It is a trite saying that all men are fallible, and though, of course, the expert intends to be absolutely impartial in his statements, there is double danger of a little fallibility in a case where the man reflects that his reward is to come from the side which engaged him.

In order to eliminate as far as possible these various harmful elements of bias and confusion, Dr. Ward advised that instead of the present system, a board of three experts be appointed in a case where medical testimony is needed; one on the suggestion of the counsel for the defense, another nominated by the counsel for the prosecution, and the third appointed by the judge. The expenses of this board are to be divided equally between the two contending sides; it is to receive in writing all questions involving medical matters, and to submit its answers to the court by the same medium. This seems to us eminently better than the present plan.

PROGNOSIS IN HEART DISEASE.—M. Leyden, after pointing out that in general the prognosis is considered as desperate, claims that sudden death from this cause is in reality much rarer than might be supposed. The following is especially to be considered:

1. *Age:* Children resist less than adults, but better still than old people in whom the situation is apt to be complicated by arterial sclerosis.

2. *Sex:* Women are less exposed to great fatigue and are also less subject to arterial sclerosis, which modifies the prognosis to some extent.

3. *Occupation:* Fatigue and laborious occupations of all kinds are an aggravating cause in all cardiac troubles and bear upon their prognosis.

Finally, the failure of digitalis is to be regarded as an unfavorable element.—*La Tribune Médicale.*

Simple Inhaler.—Roll a piece of paper in the form of a cigarette, fix it with gum, insert a small wad of cotton on which is poured a few drops of the volatile substance to be inhaled, menthal ecualyptus, and the like, and the instrument is complete.—*Practitioner.*

Electrolysis.—R. A. Gibbons, M.D. (*The Practitioner*), furnishes a paper on Electrolysis in the treatment of Some Chronic Uterine Affections, and after detailing the histories of ten cases thus treated, with more or less success, concludes by saying that he is not an enthusiast in any one special method of treatment, but is firmly convinced that when properly and judiciously employed we have in electrolysis a most powerful therapeutic agent at our command.

Turpentine in Post-partum Hemorrhage.—Mayne has used oil of turpentine in post-partum hemorrhage for several years, with very good results. When the usual means, such as kneading the uterus, insertion of the hand, cold, subcutaneous injections of ergotin, etc., have proved ineffectual, contraction of the uterus followed immediately after insertion of a piece of linen, saturated with oil of turpentine, into the uterus, and bringing it in contact with the walls; and all hemorrhage ceased. In several cases where the patients were nearly pulseless it acted also as a stimulant. He never saw it fail, and it is well borne by the patients.—*Med. Zeitung.*

Mammary Fistula.—Nicolai (*Monatschrift*) reports a case of fistula of the left breast, the mammary gland being healthy. The fistula had resisted treatment for four years. The patient then went to a dentist on account of trouble with the first lower left molar; to which an antiseptic dressing was applied. The next day the discharge from the fistula had the odor of the antiseptic used in the tooth. To render the matter certain, he injected into the root of the tooth a solution of cochineal. The tooth was extracted and a flexible probe introduced, when the fistula was found to extend down to the base of the inferior maxillary bone, along the border of the sterno-cleido mastoid, perforating the strong platysma fascia, and entering the breast above the pectoralis major, opened at the nipple. It closed in twelve days.

Headaches.—E. Jones (*The Practitioner*), in an article on Diagnosis and Treatment of Headaches, finds that for acute low pressure headaches this is good:

℞.—Spiritus ammoniæ aromat. . . . ℥ss.
Spiritus chloroformi . . . . . ♏x.
Aquæ . . . . . ad. ℥j.—M.

In recurrent high pressure headaches he finds alkalies most beneficial.

℞.—Sodii bicarbonatis . . . . . gr. x.
Ferri et ammonii citratis . . . . gr. v.
Spiritus chloroformi . . . . . ♏x.
Aquæ meuthæ viridis . . . . ad. ℥j.—M.

Sig.—To be taken three times a day, half an hour before meals.

William Dayton, M.D. (*Post-Graduate*), writes strongly in favor of nose breathing, and on the various dangers consequent to the habit of breathing through the mouth, claiming also that the nose receives far less attention as an organ than it deserves.

Cystitis.—T. M. Madden (*Archives of Gynæcol.*), says that during the past year twenty-eight cases of cystitis have come under his observation, some of which had resisted years of treatment, but which readily yielded to the following: If the case is complicated, of course the complication is first to be removed. Next, he thoroughly dilates the urethra until he can introduce his index finger and paralyze the contractility of the sphincter vesicæ for a time. He repeats this as often as is necessary. He thus gains that rest for the bladder secured by Emmet's method of making a vesico-vaginal fistula, and in a much less dangerous and objectionable way. It may sometimes be advisable cautiously to remove the proliferating vesical mucous membrane with a dull curette. Lastly, he makes a local application of carbolic acid; saturating a pledget of cotton with the officinal glycerole of carbolic acid and inserting it into the bladder. It is retained here till every part of the bladder has firmly contracted on it, after which it is removed and the urethral canal brushed by a similar application. Pain may be obviated by a 10 per cent. solution of cocaine. Two or three applications, at intervals of a week, generally effect a cure.

W. C. Wheeler (Alabama *Med. and Surg. Age*), in a paper on Dentition, remarks that we pay too little attention to our small patients, and that, for instance, the painstaking practitioner who safely brought William of Orange through a perilous dentition did as noble a work for humanity, and one meriting as much approbation, as those operations which have been performed these later years on noted characters, and which have commanded the attention and the admiration of the world.

Ligation of Common Carotid and Subclavian.—F. T. Meriwether, M.D. (*Annals of Surgery*), performed the simultaneous ligation of the common carotid and the right subclavian for a rapidly growing aneurism of the ascending aorta.

The common carotid was tied about half an inch below the omo-hyoid, as that muscle was higher than usual; and the subclavian was ligated in its third part.

Before the operation, from which the patient recovered without an untoward symptom, she complained of great pain in the back, deafness in the right ear, and pain and difficulty on swallowing. On the seventeenth day she left the hospital apparently cured, at any rate having none of these unpleasant symptoms.

This makes the seventh similar case on record. Of the other six, three died directly or indirectly from the operation or the disease, whilst the other three recovered.

A. M. Cartledge, M.D. (*Am. Prac. and News*), advocates the use of bichloride of mercury in anæmia, especially when given with hydrochloric acid.

Hernia of Pleura into Neck.—In *Annals of Surgery*, G. R. Fowler, M.D., reports a case of this character: A child of three months, and with a history of previous good health, had an attack of acute bronchitis accompanied with severe coughing. After recovering from this a swelling was noticed on right side of neck, which became larger when the child cried or coughed. In a month afterwards a similar swelling appeared on the left side. Six months after the first appearance the child was brought to the hospital, at which time there were two well-marked swellings on the neck, each of which nearly disappeared on inspiration, but became large and tense on expiration. She had constant dyspnœa and aphonia.

Another attack of bronchitis carried her off in three days. The autopsy showed that the protrusions of the neck were part of an enormous sac connected with the upper part of the right lung. When distended it occupied a large part of the right pleural cavity and the anterior mediastinum between the thymus and pericardium. The sac, which contained odorless air, and had thin, smooth, glistening, and transparent walls, had pushed its way behind the trachea and upwards toward the anterior surface of the neck, producing the swellings noted. These swellings were the result of a rupture of the primary bronchus in the upper lobe of the right lung, and the air escaping underneath the pleura separated it from its pulmonary attachment.

Raymond's Disease.—The *Lancet* mentions a patient suffering from attacks of local asphyxia in both hands and feet, independently of exposure, sometimes three or four in a day, alternating with paroxysmal attacks of epigastric pain and vomiting, usually followed by slight jaundice. There was no hæmatinuria, though albumen as well as bile had been present in the urine after an attack; but no reaction could be obtained after the guaiacum test. In the interval the hands and feet usually recovered their own natural color and warmth. The local syncopic and asphyxial stages were usually well defined. The palmar aspect of the fingers was affected throughout, but only the dorsal surface of the terminal phalanges and nails; the toes of both feet were involved on the under surface, but to a less marked extent than the fingers, which sometimes became almost black; no pain was complained of in the hands or feet during the attack. The patient's age was forty-eight; she was a married woman; had had the attacks in the fingers about four months, and had not suffered previously from cold fingers or chilblains, not being especially exposed to damp or cold. She never got her living by washing. She had nine children living. The catamenia were still regular. The family history was good. No rheumatism, gout, or ague; abdominal tenderness over epigastrium and left hypochondrium; field of vision good.

Oscar Dowling, M.D. (Alabama *Med. and Surg. Age*), reports a case of morphine poisoning which, after having refused to yield to the ordinary treatment, was saved by the use of nitroglycerin hypodermatically, and electricity.

In *Med. Press and Circular* is reported a case of total extirpation of the larynx for epithelioma, with recovery and a useful voice. The vibratory structure in making the voice "appeared to be the mucous membrane of the pharynx running backward from the epiglottis."

Albuminuria.—J. G. Adami (*The Practitioner*), in an able paper on the Functions of the Glomeruli of the Kidney, holds that the secretion of urine depends not so much on the blood-pressure as upon the rate of flow of the blood through the kidney, and that albuminuria is the result of a lowered vitality of the glomerular epithelium, thus allowing the thicker constituents of the blood to transude.

Mycosis Narium.—Hugo Summa, M.D. (St. Louis *Med. and Surg. Journ.*), reports two cases of this rather rare trouble, both caused by the pseudo-parasitism of the sarcophagous larvæ of the blue-bottle fly.

The first was that of a gardener, who, seven days after taking a nap on the ground, felt pain in his nose, which rapidly increased, spreading, finally, over his whole head. Meanwhile, worms dropped from his nose, three or four at a time, amounting to several hundreds during the six days before the writer saw the case. Morphine was given for the pain, and the nose was syringed with a 1–2000 bichloride solution twice a day, the man including in his diet, the while, raw eggs in order to avoid the possible toxic effect of the corrosive sublimate. In eight days the patient was entirely cured.

The second case, a man of thirty-four, was brought to his office complaining of a severe headache, insomnia, anorexia, and constipation. He was hardly able to see with his left eye. His nose and the surrounding parts, especially on the left side, were swollen and of an erysipelatous appearance. On examining the patient's mouth he found an ovoid-shaped hole corresponding to the palatine suture, and partly in the soft and partly in the hard palate. This hole was an inch long and one-quarter broad, and in its depth he found great numbers of maggots. The stench was so indescribably bad that the doctor had to vomit five times before he could screw himself up to the business of picking the maggots out. He ordered injections of 5 per cent. solution of carbolic acid, which had no appreciable effect on the stench; for, on coming back in the evening, Dr. Summa was again compelled to throw up a few times before he was able to pick out fifty maggots more from the man's mouth and nose. He then gave the case to another physician, because his non-nervous system was too much affected; in fourteen days he saw the patient walking about, and on questioning him as to the history of the case, found that the man, while hunting, had slept out-doors several nights, a few days before the trouble appeared.

Medical News and Miscellany.

DR. L. F. FLICK appears to be the first to reach the scene of disaster.

JEFFERSON COLLEGE HOSPITAL has thrown open its doors to the sufferers.

THE Medico-Chirurgical ambulance is kept busy gathering stores for the sufferers.

THE physicians who left Philadelphia to go to Johnstown have been compelled to go by Baltimore, Buffalo, or Wheeling.

IT is probable that the meeting of the State Society will be postponed, as few of the members have been able to reach Pittsburgh in time.

DR. L. T. BEAN and his brother, the most prominent and influential eclectic physicians in the State, are said to have lost their lives at Johnstown.

AMONG the first to tender their services to the Governor were the physicians of the Hahnemann Hospital: Drs. Rhodes, Garrison, Bryant, Bayley, Schnader, Ward, Ellis, Thompson, Crock, Mercer, Messerve, Gardiner, Reading, and Mohr.

IT is to be hoped that the suggestion of cremating the bodies of the flood's victims will be adopted. Otherwise there are grave dangers of pestilential disease, not only in the Johnstown district, but from the pollution of the water supplied to towns below.

THE danger to the country of allowing the savage tribes of Europe to form communities among us, has been shown by the action of the Slavonians in the Conemaugh Valley. If these people were dispersed among the other inhabitants, they would have some chance of becoming tamed, if not civilized.

AMONG the names reported as lost at Johnstown we regret to see the following: Drs. S. Y. Beam, W. C. Beam, L. T. Beam, Blair, Jr., T. T. Beane and family, Cooper, of Meadville, and wife, J. K. Lee, John Lowman, Marbury, Poland's two children, Phillips, mother, two sisters, J. C. Wilson, H. R. Wilson, G. W. Wagner, wife, three daughters; Mrs. Dr. Reedan, Dr. St. John.

WITH Dr. Forbes' party are Drs. A. Hewson, Jr., Shober, Packard, Green, Miller, Wood, Fussell, Sweet, and Miss Dr. Alexander. Dr. Fussell had two sisters at Johnstown.

A second party equipped by Jefferson College consisted of Drs. Horwitz, Ashton, Da Costa, Coplin, Williams, and Talbot.

THE Red Cross Association has taken the storerooms at 1821 Market Street, and is actively engaged in shipping stores. The following physicians volunteered to go under the auspices of this Association: Drs. C. Berens, Read, Chrystie, Cochran, Grimm, Bradford, Baker, Tyson, Milliken, Deaver, Gross, Greenwalt, Morris, Penrose, Van Pelt, Wood, Allen, Wharton, Willard, White, Grow, Porter, Green, Barney, Conrad, Loft, and Peltz.

The committee in charge of the work here is composed of Mrs. Pancoast, Joseph, Nardyz, O'Neil, Budd, Carter, and Miss Merrill.

Drs. Hummel and Hare have gone to select a site for a temporary hospital.

PINE GROVE colts are dying of scarlatina.

REPORTS from the yellow fever centers are favorable.

LEDERACHVILLE, Montgomery County, has diphtheria.

LUYS cures facial neuralgia by the use of rotatory mirrors.

YELLOW FEVER is reported to be very bad in Vera Cruz, Mexico.

SIR MORELL MACKENZIE is to sue the London *Times* for libel.

ARE perfumes altogether without effect upon the health of infants?

DIPHTHERIA has appeared among the horses at the Penn Farm, Bucks Co.

DR. CHARLES S. TURNBULL has just returned from a pleasant trip to California.

BROOKLYN has lost one of her brightest physicians in Dr. Frank W. Rockwell.

SACCHARIN in alcohol, 1 to 50, is an effectual local application in curing thrush.

GENERAL SCHENCK is said to have been cured of Bright's disease by the milk diet.

A NUMBER of valuable horses have died recently in this county from tetanus.—*Ledger.*

THURSDAY last was Donation day at the Jewish Hospital. A large amount was realized.

DR. WALTER G. HAMMELL has removed to Philadelphia, and opened an office at 1310 Walnut Street.

SMALLPOX is making terrible ravages in Guatemala, and among the Okanagon Indians in Oregon.

DR. C. P. POTTS, of the University Hospital, expects shortly to leave Philadelphia for Washington Territory.

DR. BELL contradicts the report that he is about to return to Texas. He has built up a lucrative practice in Philadelphia.

THE grand jury has decided that chloroform is not legally a poison, as it does not cause death in doses of sixty grains or less.

CHESTER is moving for the removal of the quarantine station from its present location. Drs. Leffman and Forwood urged the removal.

WE are glad to see that the State Board of Health is taking steps to prevent the unauthorized use of its name by advertisers in its official organ.

A LONDON barber advertises that all implements used in his tonsorial palace are kept in an antiseptic condition by a strict observance of Listerism.

THE *British Medical Journal* is entirely too prosperous to suit its rivals, and they have stirred up an opposition to Ernest Hart's management, which threatens to strike at the sources of its prosperity. They wish to cut off part of the advertising patronage.

CORPORAL TANNER is making a clean sweep of the Pension Examining Boards; the *personnel* of which is being changed everywhere.

DR. R. J. LEVIS, who is summering with the Duke of Sutherland, instead of at Cedarcroft, has lately bought a winter home in Florida.

DR. E. L. VANSANT has resigned his position in the Medico-Chirurgical College, and has been elected Demonstrator of Histology at the Jefferson.

A PATIENT with lung-ail, dreading the jolting of the cars, has started to walk from Harrisburg to Philadelphia, where he desires to enter a hospital.

DR. S. P. MOORE, who was Surgeon-General of the Confederate States, died suddenly last week at his residence in Richmond, Va., of congestion of the lungs.

DR. CONNOR, President of the Ohio State Medical Society, wittily compared the Presidential Address to the appendix vermiformis—a useless survival of a once important organ.

A *Ledger* correspondent makes the very sensible suggestion that there might be a new chair added to the medical colleges, whose occupant shall teach the art of palatable dietetics.

MR. BURROUGHS, of Burroughs, Wellcome & Co., is credited with the idea of charging air supplied to buildings by a fan with antiseptic vapor. If the air is pure, why medicate it?

CAIRO (Ill.) courts are said to have sittings from midnight to dawn, because that time alone suits her enterprising but malarial citizens to make engagements which may not be shaken off.

DR. MARY DIXON JONES, of the Brooklyn Woman's Hospital, is accused of having a mania for operating, and to have found uterine cancers in about every woman who entered her little parlor.

THE cantankerous race which is always kicking up trouble by questioning the truths whose foundation is secure, are now trying to deduce the leprosy of the Sandwich Islands from syphilis.

HOT water is said to be a popular remedy for inflamed eyes.

Some years ago it was cold water.

The eye is not a good field for amateur doctors.

READERS who have not received all the numbers containing Dr. Billings' article on Yellow Fever Germs should send at once for the missing copies, as they are rapidly disappearing from our files.

The Medical Press is endeavoring to awaken a sluggish race to the danger from the spread of leprosy in India. There are no lazarettos for the 120,000 lepers in that part of Her Majesty's realm.

DR. HAMMOND recommends the "water-monkeys" used in the tropics instead of ice to cool water for drinking. This utensil is invaluable in the South, but those who are accustomed to ice water, are not very likely to take kindly to it.

DR. MARY MOREY, of Philadelphia, has been added to the medical staff at the State Hospital for the Insane. Dr. Morey takes the place in the pathological department made vacant by the resignation of Dr. Ida V. Reed—*Press.*

DR. SAMUEL G. LANE, one of the most widely known physicians and surgeons in Chambersburg, died there yesterday, of apoplexy, after a short illness, aged sixty-two years.

S. WEIR MITCHELL has taken time from his busy life to write another book. This time it is a volume of poems entitled "The Cup of Youth," published by Houghton, Mifflin & Co., Boston.

FOR the convenience of English-speaking students, the Vienna *Weekly News* has opened an inquiry office near the general hospital, where information as to lectures, lodgings, etc., may be obtained free.

THE physiologies will have to be overhauled. A Russian has been varnishing people, and finds that covering the skin with an impermeable preparation causes no discomfort in man, though it kills rabbits.

VETERINARY surgeons are now required to register before they are allowed to practise in Pennsylvania. Any one who has practised for five years or more can register within six months. After that time none but graduates are eligible.

SOME very unwise talk has been indulged in by some of our physicians concerning the swallowing of tacks. People of ordinary intelligence would suppose from their statements that this is a very harmless and rather beneficial amusement.

DR. WILLIAMS (St. Louis *Globe-Democrat*) says that the reason hearty people have pneumonia more frequently than weakly ones is because the former do not take the same care of themselves as the latter. This is not confined to pneumonia.

A NEW YORK florist contracted lead poisoning by biting off the ends of tin-foil used in wrapping up the ends of the bouquets.

Another got the same disease by drinking beer from bottles which had been cleaned with shot.

OBESITY.—Stallard (*Occidental Med. Times*), reports a case of obesity, for which he prescribed a diet exclusively of meat, fat and lean, with the further injunction to drink at least two quarts of hot water daily, taking it before and after meals. In three weeks the weight was reduced from 199½ to 175 pounds.

RUSH MONUMENT COMMITTEE.—The Rush Monument Committee will meet in Right Gallery Room, at Music Hall, Newport, R. I., on Tuesday, June 25, at 1 P.M., or immediately after adjournment of the Morning Session of the American Medical Association.

The attendance of others interested in the project is invited.

Collections and subscriptions should be forwarded to the Treasurer, Dr. Joseph M. Toner, 615 Louisiana Avenue, Washington, D. C., before June 15.

ALBERT L. GIHON, M.D.,
Chairman, R. M. C.

FORTY-EIGHT hospitals in Philadelphia have made reply to the inquiry of the State Board of Health in regard to the disposition of rags and bandages. Thirty-three reported that they burned all bandages, three disinfect them, and twelve wash them before sale. The Board recommends burning in all cases. —*Record.*

THE proposition to remove the Academy of Natural Sciences to the University grounds was rejected by a vote of 68 to 3. It is, perhaps, just to explain that this does *not* represent the unpopularity of the University among Philadelphia scientists; and the failure of that educational institution to obtain recognition from the Academy.

A CREDITABLE victory was won for conservative surgery and the Episcopal Hospital in the case of Customs Inspector, James McCann; who was terribly crushed by a train last February, six cars running over him. He was discharged last Friday in very good condition, and in a fair way to complete recovery. All four limbs were broken.

A RECENT inspection made by Dr. Taylor of a house in West Philadelphia in which typhoid fever had occurred, showed that the family made use of the water from a well which was contaminated by surface and cesspool drainage

It would, perhaps, not interfere unduly with the liberties of the people if all wells in built-up portions of the city were filled up.

DRS. BEECHER, Bell, and Horwitz have resigned their positions as Joint Demonstrators of Anatomy at Jefferson Medical College, and Dr. A Hewson, Jr., has been elected to fill the place.

Dr. Beecher is a graduate of the College in the Class of 1867, and has spent some eleven years as assistant demonstrator, and demonstrator in the anatomical room. He is well and favorably known to many students and physicians throughout the country to whom he gave instruction.

DEPARTMENT OF THE INTERIOR,
CENSUS OFFICE.
WASHINGTON, D. C., May 1, 1889.

To the Medical Profession: The various medical associations and the medical profession will be glad to learn that Dr. John S. Billings, Surgeon U. S. Army, has consented to take charge of the Report on the Mortality and Vital Statistics of the United States as returned by the Eleventh Census.

As the United States has no system of registration of vital statistics, such as is relied upon by other civilized nations for the purpose of ascertaining the actual movement of population, our census affords the only opportunity of obtaining near an approximate estimate of the birth and death rates of much the larger part of the country, which is entirely unprovided with any satisfactory system of State and municipal registration.

In view of this, the Census Office, during the month of May this year, will issue to the medical profession throughout the country "Physician's Registers" for the purpose of obtaining more accurate returns of deaths than it is possible for the enumerators to make. It is earnestly hoped that physicians in every part of the country will coöperate with the Census Office in this important work. The record should be kept from June 1, 1889, to May 31, 1890. Nearly 26,000 of these registration books were filled up and returned to the office in 1880, and nearly all of them used for statistical purposes. It is hoped that double this number will be obtained for the Eleventh Census.

Physicians not receiving Registers can obtain them by sending their names and addresses to the Census Office, and, with the Register, an official envelope which requires no stamp will be provided for their return to Washington.

If all medical and surgical practitioners throughout the country will lend their aid, the mortality and vital statistics of the Eleventh Census will be more comprehensive and complete than they have ever been. Every physician should take a personal pride in having this report as full and accurate as it is possible to make it.

It is hereby promised that all information obtained through this source shall be held strictly confidential.

ROBERT P. PORTER,
Superintendent of Census.

THE NEW QUARANTINE STATION AT THE ENTRANCE TO DELAWARE BAY.—It will be remembered that Congress, at its last session, appropriated a considerable amount of money for the equipment of seven quarantine stations, five for the Atlantic coast and two for the Pacific. Of this appropriation about $75,000 was assigned for the establishment of a thoroughly equipped station for the protection of the Delaware Bay and River. Heretofore the only safeguard against the introduction of contagion below the Lazaretto has been the little Hospital of the United States Marine Hospital Service near Lewes, simply assigned for the treatment of sick or wounded seamen, with no adequate provision for the isolation of those suffering from infectious diseases. So well has this service been administered, however, that it has, on several occasions, detained and disinfected pest-laden vessels and their crews, and thus stayed at the threshold cases which might have resulted in disastrous epidemics had they gained admission. At or near this point, the Legislature of Delaware has offered to cede to the United States the land necessary for the proposed buildings and appurtenances. The Secretary of the State Board of Health of Pennsylvania, Dr. Benjamin Lee, has been designated a Commissioner on the part of the United States to meet Commissioners appointed by the State of Delaware, and in conjunction with them to locate and fix the boundaries of this Reservation. This preliminary will be speedily settled, and work will be begun at an early date.

THE turnkey of the Peoria jail has a cure for delirium tremens. He rubs the patient with capsicum; and in the enthusiasm and singleness of purpose with which the latter scratches himself he has no time to think of snakes. One day of this treatment is sufficient for any ordinary case.—*Medical World.*

DIAGNOSIS.

Bright conjunctiva and restless eye,
Hectic flush and audible sigh,
Hollow chest and thin pale face,
Obviously, one of tubercular race.

TREATMENT.

Plenty of nourishment, rest from toil,
Fellows' hypophosphites, cod liver oil;
These may retard the dread disease,
Or give to breathing and cough some ease,
Smooth the way to dreaded grave,
Though out of our power the life to save.

—*Hospital Gazette.*

THE North Texas Medical Association meets in Paris, Tex., Tuesday, Wednesday, and Thursday June 11, 12, and 23, 1889. Among the attractions of the meeting will be the following papers:

Section on Surgery.—1. The Treatment of Diseases of the Cæcum and its Appendix, Bacon Saunders, M.D., of Bonham, Tex. 2. Surgical Interference in Mastoiditis, J. H. Smith, M.D., of Dallas, Tex. 3. Mortality of Amputations, W. F. T. Savage, M.D., of Mt. Pleasant, Tex.

Obstetrics and Gynecology.—1. Lacerated Cervix Uteri, J. F. Hooks, M.D., of Paris, Tex 2. Lacerated Perineum, S. F. King, M.D., of Bells, Tex. 3. Puerperal Eclampsia, R. R. Walker, M.D., of Paris, Tex.

Practice of Medicine.—1. Dysentery, V. A. Howeth, M.D., of Gainesville, Tex. 2. The use of the Microscope in the Diagnosis of Disease, F. E. Yoakum, M.D., of Greenville, Tex. 3. Cerebro-spinal Meningitis, T. G. Bates, M.D., of Anna, Tex.

THE esteemed *Ledger* relates as an "amusing" case that of a man who was brought into a city hospital suffering from the effects of an alleged epileptic fit. The alleged medical man concluded that the patient was shamming, on the inconsequent grounds that he was able to talk; whereupon the doctor ordered a poker to be heated, saying that he proposed to burn the man's back. The latter, becoming naturally alarmed, tried to escape from his persecutors, when the doctor caught him, drew a large knife across his neck and at the same time poured warm water down his back. The man gave a loud yell and fled from the building. It is difficult to decide whether the exhibition of ignorance or brutality were greatest. If the account be true, the man has good grounds for an action against the parties who maltreated him. It is fortunate for them that there was not a repetition of the tragedy which followed the same trick in Edinburgh, where the victim died of fright.

HALL'S HAIR RENEWER.

℞.—Sulphur precipitated . . . . . 1 ʒ.
Lead acetate . . . . . 1 ʒ.
Salt . . . . . 2 ʒ.
Glycerin . . . . . 8 fʒ.
Bay rum . . . . . 2 fʒ.
Jamaica rum . . . . . 4 fʒ.
Water . . . . . 16 fʒ.

As delicate a charity as I remember was the act of a gruff, taciturn old physician in a Colorado mining town. A poor, aged parson was carefully attended by the irritable doctor. When the preacher had sufficiently recovered to dispense with further medical attention he asked for his bill. "Your bill? Here it is," said the doctor, opening his pocket-book and handing the minister's wife a ten-dollar bill.—*America (Chicago).*

A YOUNG LADY'S SINGULAR AFFLICTION.—Physicians report a singular case in Cabarrus County, N. C. A young lady has been troubled with utter speechlessness. She visits frequently friends at a mineral spring in Stanley County. Several hours use of the water restores her speech to such an extent that no one could detect any deficiency in that respect. After being away from the springs several days the affliction returns. Thus far this peculiar disease has baffled all medical treatment.—St Louis *Globe Democrat.*

THE DIETETIC GAZETTE.—They all say the same thing. Here are three of them for example:

"We have very thoroughly demonstrated the fact that to advertise in *The Dietetic Gazette is a paying investment;* while we have extreme satisfaction in the belief that we are being placed before the *entire medical profession.*"

PARKER, STEARNS & SUTTON,
228 & 229 South Street, New York.

"We have every reason to believe in *The Dietetic Gazette* as a means of attracting the attention of physicians in all parts of the Union."

J. C. BAKER & CO.,
815 Filbert Street, Philadelphia.

"It is with great pleasure that we state to you that our advertisement in *The Dietetic Gazette* has proven most effectual, and that we have received more replies from that source than from any other journal with which we are connected as advertisers. *We believe it to be the best medium of the medical journal kind in this country.*"

THE J. P. BUSH MANUFACTURING CO.,
("Bovinine.")
No. 2 Barclay Street, Astor House, New York.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 28, 1889, to June 3, 1889.

BILLINGS, JOHN S., Major and Surgeon. Is authorized to make, by direction of the Secretary of War, in connection with his duties as Supervisor of Mortality and Vital Statistics of the Eleventh Census, such journeys as may be ordered by the Superintendent of the Census, provided that, in each case, the approval of the Surgeon-General shall be obtained; and provided further, that the journeys shall involve no charge against the fund for transportation of the Army. Par. 12, S. O. 122, A. G. O., May 27, 1889.

BROWN, PAUL R., Captain and Assistant-Surgeon. Is granted leave of absence, by direction of the Secretary of War, for six months on account of sickness. Par. 13, S. O. 122, A. G. O., May 27, 1889.

WILSON, GEO. F., Captain and Assistant-Surgeon. Resignation has been accepted by the President, and took effect May 31, 1889.

FISHER, WALTER W. R., Captain and Assistant-Surgeon. The leave of absence for one month granted by S. O. 30, c. s., Department of California, is extended fifteen days. Par. 3, S. O. 37, Headquarters Division of the Pacific, San Francisco, Cal., May 22, 1889.

GLENNAN, JAMES D., First Lieutenant and Assistant-Surgeon. Is relieved from duty at Willet's Point, N. Y., by direction of the Acting Secretary of War, to take effect June 1, 1889, and will proceed to Fort Riley, Kan. Par. 5, S. O. 121, A. G. O., May 5, 1889.

Clinical Lectures.

MITRAL REGURGITATION. ANGINA PECTORIS.

(Delivered at the Philadelphia Hospital, May 22, 1889.)

BY JAMES B. WALKER, M.D.,

Professor of Theory and Practice of Medicine in the Women's Medical College of Pennsylvania.

GENTLEMEN: I show you to-day the colored man whom last week you saw in a water-logged condition suffering with orthopnœa. As you see, he still cannot lie in a recumbent position, although he is comfortable in a semi-recumbent posture. The change in his condition is marked, however, since I showed him to you last week. The dropsical condition has now almost disappeared, though there is still some pitting on pressure. The feet are scarcely œdematous, while the thighs have not been especially so at any time. A glance at the measurements of the body will more clearly demonstrate the improvement in his condition. On entrance he measured around the instep 12 inches, now 10½; above the ankle, 10¾ inches, now 8½; around the calf, 17 inches, now 13; around the middle of the thigh, 23 inches, now 19½; around the abdomen, 41 inches, now 37.

His treatment has consisted in the use of concentrated salines, administered in the morning one hour before eating, and in the use of digitalis and caffeine. These relieved the dropsy considerably, but did not much affect the dyspnœa, to relieve which some sixty ounces of fluid were removed by paracentesis. The right pleura still contains considerable fluid, but that present in the abdominal cavity and the tissues of the body has been removed by the treatment. This dropsy is simply an effusion, and is not the result of any inflammatory action.

There have been some peculiarities about the case. The first of these has been the acuteness of his attacks. Seven or eight weeks ago he was admitted to the hospital with a large accumulation of fluid in his chest. After the removal of this by paracentesis he left the house, but returned three weeks ago in the condition that you noticed when brought before you last week. In a short time he will probably be relieved of his dropsy and will leave in a comfortable condition, but it will require only a little exposure to precipitate another attack.

His pulse has greatly improved in tone and rapidity. Its quality indicates a better condition of the arterial system. He still has his lesion of mitral regurgitation, and just as much as at first, it being a condition which does not vary much with treatment. The crippling of the heart is a permanent thing, but the tone of the heart muscle can be considerably bettered by treatment. Digitalis and caffeine are still indicated by the rapidity of the pulse, but later we shall give him nitroglycerin or some one of the nitrites, preferably the latter. Strophanthus may be used, but it is not as reliable a diuretic as digitalis. It is not wise to trifle with substitutes for digitalis, but they may be administered alternately with that drug.

It is best in bad conditions to depend entirely on digitalis. If it does not show some result in two or three days it will not do any good, and then we may substitute some one of the others. An increased amount of urine and a lessened action of the heart indicate a good action of digitalis. If we do not observe this, it may be well to substitute for the digitalis a preparation of strophanthus. Generally I do not believe in tapping for heart troubles, but would rather rely upon diuretics and heart tonics to remove the effusion, only resorting to operative measures when signs of danger appear.

In a few days the patient will be in a fairly good condition and able to leave the house. There is no form of dropsy so amenable to treatment as the dropsy of heart troubles, but at times we cannot get any marked improvement for the reason that the heart is too far gone and the weakness of the patient is too extreme. Still we should not permit this weakened condition to prevent us from using every means in our power to alleviate the suffering of our patients, and the concentrated hydragogue salines, even here, may be used, for they seem to act as tonics while they remove the dropsy.

This second patient is the Italian whom I also showed to you last week as suffering from the same condition as the colored man, namely, mitral regurgitation. He also, as you may notice, is considerably improved, and though his heart's action is rather rapid, it may be accounted for by his dread at appearing before this large assembly. He also has been placed upon digitalis and caffeine, with the result you see.

I now show you a case of more than ordinary interest. He is a young man, twenty-two years of age, a laborer. He gives a good family history, and has himself been remarkably free from disease. He has had none of the affections of childhood, and never suffered from rheumatism. Six years ago he had an attack of intermittent fever, which soon passed off. He has always been a hard worker. Three months ago, while working in his store, he suddenly fell to the floor and remained unconscious for some time. On awakening he found he was affected with a right-sided hemiplegia. All power of voluntary motion was gone, and he was confined to bed for two weeks. This passed away entirely, however, and at present no trace of it remains. He has of late spat up blood, and is quite weak.

This history describes an attack of paralysis of the right side, of which no physical signs at present can be seen. An examination of the patient's heart reveals a most interesting condition. The apex beat can be seen at least one inch to the left of its normal position, and in the sixth instead of the fifth interspace. Its impulse is exaggerated, and can be seen over an extended area reaching from the epigastrium down to the umbilicus and up as far as the third rib. The hand placed over this region, and especially over the point of greatest intensity of the impulse, appreciates a systolic thrill. This is a very unique case of a *ventricular systolic thrill.* I have never before felt a thrill over the ventricle synchronous with the systole. There is also heard over the point of the apex beat a smooth systolic murmur.

A mitral systolic thrill is very unusual; a diastolic thrill associated with a presystolic murmur due to a roughened mitral valve is very common, so much so that the thrill suggests this murmur at once to the physician. Here is a thrill associated with the systole. The murmur here present is very interesting. Listening over the apex we get a high-pitched, musical, whistling murmur, which is smooth, and, associated with this, over the region of the pulmonary cartilage, is a low-pitched, rough, very regular vibratory thrill sounding like a drum-beat. You might easily imagine you had a fife-and-drum corps here.

The question at once arises, Is the systolic murmur a pulmonary murmur? I think not. The apicial murmur indicates a leakage through the mitral orifice. All high-pitched murmurs are caused by leakage through small orifices, and in this case it is due to a mitral regurgitation. The mitral direct murmur is the lowest pitched murmur we have, because the aperture is large and the power which forces the blood is small. The murmurs in our present case blend and are not separated, and, I think, are produced by the same cause. The murmur over the base of the heart is due, possibly, to the blood throwing into vibration the anterior cusp of the mitral valve, which is also the posterior cusp of the aortic valve. These vibrations are very regular. The high-pitched murmur is due to a regurgitation, the blood passing through a narrow orifice.

We may ask, What else might this be? It might be an aortic direct murmur. Two systolic murmurs mean usually, aortic direct and mitral regurgitant. It is not aortic direct, however, because it is heard loudest below the aortic cartilage, and not at that point, as would be the case were the lesion situated there. It is true that it is transmitted to the vessels of the neck, but not as loudly as if it were due to a simple aortic direct murmur. Then, again, it might be due to the blood whirling in a dilated left auricle and impinging on the roughened, tesselated walls. Or it might be due to an aneurism of the heart wall, a basic aneurism, especially as it is associated with a heart thrill. This is most decided at the apex, while the coarse murmur is heard best at the base. Again, it might be due to a perforated interventricular septum, due to a small aneurism which has burst and formed a communication between the ventricles. This case does not strike me, however, as an aneurism, because the thrill is so extensive.

It might be asked, Is this a pericardial thrill? I say it is not, because a pericardial thrill and murmur are not synchronous with the heart sounds, but are due to the motion of the heart wall against the pericardial sac, and this occurs just as the mitral and aortic orifices are closed, as has been shown by investigation, and when there is no attempt on the part of the ventricles to contract. A pericardial friction sound follows the first sound of the heart; and then, again, a pericardial friction sound as rough as this would be associated with a diastolic thrill as well as a systolic.

I would, therefore, say that the condition present in this case is due either to a regurgitation of blood

into the cavity of the left auricle or to an aneurism of the heart wall.

I now bring before you a man who has been a soldier, and also an excessive user of tobacco. He suffered from rheumatism in 1873, being confined to bed at that time for twenty-three weeks. Later he was suddenly attacked with hemiplegia, which was followed by a severe pain in the heart, that organ feeling as though grasped in a vise. This pain extended up into the left shoulder and down the arm as far as the elbow. The hand became numb and cold. This attack has recurred since at intervals, the period of relief becoming shorter and the frequency of the attacks increasing.

From this history we can conclude that we have here a case of angina. There is a true and a pseudo angina. As the history indicates, these attacks are true angina pectoris. There exists here a condition of mitral regurgitation, which, together with the history of rheumatism, seems to indicate a true angina.

The gravity of an attack of true angina varies greatly. In its nature the disease is supposed to be a functional trouble in the ganglionic centers in the heart wall. In some instances there have been found enlarged bronchial glands pressing on these centers or on the phrenic or pneumogastric nerves. Then, again, degeneration has been found in the heart ganglia, and with this condition we have developed a pain. In some cases there are no pathological conditions, and then it seems to be due to an enervation of the organ.

As to the cause of this condition many cases seem to be due to atheroma of the aorta or of the coronary arteries, or it may be due to vaso-motor spasm of the coronary branches. In many cases there is coldness of the extremities, showing a general vaso-motor spasm. The spasm involves the muscles of the arterial walls, and not of the heart wall itself. As regards the associated symptoms of pain extending down the arm, this is attributed to a reflex involvement of the plexus supplying the arm. In very rare instances does it involve both right and left side, and rarely the right alone.

The prognosis of angina pectoris varies with the condition which produces it. The treatment includes the treatment of the spasm and that of the interval. Dr. Ringer first suggested the use of nitrite of amyl to relieve the spasm of the arterial muscles, which he supposed existed. Inhalations of this drug are followed by the greatest of relief in most cases. The patients should carry capsules containing it in their pockets for instant use. Hypodermatics of morphine may be safely resorted to in most cases, in doses of one-sixth to one-quarter of a grain. The patient should be placed in a sitting posture, and not laid down, as this gives most relief. This is the treatment for ordinary cases, but the patient may pass into a condition of general vaso-motor spasm with collapse. In such a case mustard blisters, pediluvia, and applications of hot water must be made, and, internally, champagne, whiskey, and the carbonate or aromatic spirits of ammonia are to be administered. Fresh air in abundance must be allowed.

For the permanent relief what must be done? In order to lessen the frequency of the attacks nitroglycerin seems to act most efficiently. The nitrites are the most interesting of the medicines of the "Pharmacopœia" to study, but they have not always answered the purpose for which they have been employed. Only those whose action is rapid are useful; the others have failed. One drop of a one per cent. solution of nitroglycerin, or a pill containing $\frac{1}{100}$ grain may be administered, and it should be pushed till we get the physiological effect, namely, the flushing of the face. One of these pills may be given thrice daily, or, if necessary, two, or even six, three times a day, stopping when flushing of the face is produced. Digitalis and strophanthus, to correct the heart troubles and tone it up, will aid in preventing a recurrence of the angina.

Original Articles.

PERSONAL REMINISCENCES ON THE SUBJECT OF ANÆSTHESIA.

(Read at the meeting of the Ohio State Medical Society, May 22, 1889.)

By H. CULBERTSON, M.D.,
Assistant-Surgeon United States Army (Retired),
ZANESVILLE, O.

Reminiscences of Experiments made and Conclusions drawn, in 1861, as to how Chloroform Produces Death.

THE article concerning this subject was read before the Ohio State Medical Society twenty-eight years ago, and published in its "Transactions" for 1861. The views expressed then hold good to-day. The cry then was "heart failure." Our article refuted this view and advocated brain failure as the death-cause from chloroform. We found that the lungs failed first, the heart invariably last by inhalation; that restoration could be effected when the lungs had ceased to act, but that this could not be accomplished after the heart had ceased to beat; that if ether were the inhalent, the animal could be restored even after the heart had ceased to beat, by artificial respiration and electricity (galvanism). We also found that immediate post-mortem examinations revealed the lungs fully expanded until the chest was opened, which caused these organs to collapse one-half to three-fourths; yet when shrunken they were engorged with blood, contained mucus, bled freely on being incised, crepitated, and floated on water; that the heart and its great vessels were distended with dark fluid, uncoagulated blood, invariably fuller on the right side of this organ; that when the heart was opened the right ventricle and auricle contracted, but not the left side of this organ; that the coronary veins were distended with blood; that the membranes of the brain were congested, but not the substance of that organ, and likewise the vessels of the spinal membranes were distended with blood, but not those of the cord; that the trachea and the mouth contained frothy mucus; that the abdominal organs and vessels were turgid with blood; that the left lung was generally more congested than the right; that during the exhibition of chloroform there was, first, excite-

ment of body, free flow of saliva, quickened pulse, contracted pupils, slowing of pulse and respiration, stupor, insensibility; finally, thready and more rapid pulse and more frequent respiration, dilated pupils, the lungs ceased, and then the heart, to act; that there were reflex spasms of muscles before death, and often after death on cutting muscles in opening the chest. That chloroform (one drachm) injected into the external jugular vein, caused distention of all the heart cavities with coagulated blood; that the endocardium was a bright pink color, not dark as from chloroform inhalation; both lungs were greatly congested, affording mucus and blood on section; the lungs were expanded, but when the chest was opened they collapsed, but not so much as from inhalation. That a drachm of chloroform gently placed about the medulla oblongata caused respiration to cease at 30, and the heart to cease beating at 45 minutes; the brain and its membranes were found to be injected on the right and pale on the left side, and its ventricles contained but little serum, and the injection was very faint in the region of the corpus callosum; lungs collapsed after chest was opened. Incision of these organs gave blood and mucus, more on the left side; the heart cavities were full, but not distended. That when the chloroform was given by the stomach, insensibility, anæsthesia and death followed, and the lungs ceased to act before the heart; the brain was congested, most in its cortex, the sinuses were full of dark blood, there was no effusion of serum; the stomach and the bowels were pale; the liver was congested and dark-red in color; the lungs collapsed when chest was opened, the right dark, the left light-red in color, the right on incision gave very little blood or mucus, the left blood and mucus freely; oxygen gas and air, introduced by bellows into the trachea, and artificial respiration failed to restore the subjects. That when the animal was killed by pithing the medulla, the lungs collapsed after the chest was opened and were pale, and more blood flowed by incision of the left lung, and the cavities of the heart were full, but not distended. It was found that chloroform did not injure the red globules of the blood so as to impair their functions; and it was concluded that chloroform first induced unconsciousness by impressing the cerebrum, then insensibility from its impress upon the sensory ganglia, then the spinal centers and respiratory and heart centers were paralyzed, as well as the sympathetic ganglia and centers, and death followed from paralysis through the affection of the medulla.

These are the main facts reported in my paper of 1861. In twenty-eight years there have been many advances in physiology and therapeutics, and to some of these we would now refer, and through these ask, how is the heart related to the subject of chloroform anæsthesia? As is well known, this organ has an inhibitory center situated in the inter-auricular septum, and connected with the inhibitory center of the pneumogastric nerves, in the medulla oblongata; impressions on these slow the heart, and those from chloroform may paralyze the action of either of these centers, and in either case increase the rapidity of the heart's action. Observation elsewhere and in our experiments shows that in the final and fatal stages of chloroform anæsthesia, both respiration and heart action become accelerated and more and more feeble, we believe, from paralysis of these centers.

These experiments have also shown that often the right auricle and ventricle as well as striated muscles, although anæsthetized, have not entirely lost their irritability, and these heart walls contract and the striated muscles also on being incised. But there is no record of contraction of the left auricle or ventricle after death from chloroform, and I have only lately found that after the heart had ceased to beat, the left heart could not be made to contract by incision or faradism applied to its walls. The left side of this organ seems to have lost its irritability, while that of the right heart is only greatly impaired. The laws of circulation would indicate the left heart most anæsthetized.

The following table shows that in chloroform anæsthesia the relative weight of blood in the lungs to that in the heart was increased, and that in death from pithing the medulla the relation was reversed:

In 4 cases,	chloroform inhalation,	heart ratio	= 1	to lungs	1.74
" 1 case	" on brain,	" "	= 1	" "	1.20
" 1 "	" by stomach,	" "	= 1	" "	1.15
" 1 "	" by jugular-vein	" "	= 1	" "	1.20
" 1 "	pithing medulla,	" "	= 1.28	to "	1.00

Thus, without the paralyzing influence of chloroform on heart or lungs, or medulla, pithing induces a greater relative weight of heart and its contained blood than of the lungs. Of course, pithing is a form of death by paralysis of the brain-centers acting on both heart and lungs, without any local paralysis of lungs or heart by anæsthetics. It is probable, therefore, that this anæsthetic increases the relative amount of blood in the lungs, and hence respiration is more impressed than the heart from lung paralysis.

But there are, as is well known now, excito-motor nerves and centers in the medulla and heart. The former, it is thought, probably end in the excito-motor ganglia of the heart, situated in the septum of the left auricle and ventricle of the dilated end of the inferior vena cava. Chloroform, paralyzing these nerves either at the centers or through the nerves peripherally in the lungs and heart, would lead to retardation of heart and lung action. But chloroform paralyzes both the excito- and inhibitory centers and nerves, and so death may result.

But a conclusion should not be drawn until the influence of the vaso-motor nerves upon this death-process is considered. According to Huizinga (see "Action of Medicine," by Isaac Ott, M.D., p. 68, 1878) there are nerves acting on bloodvessels as follows:

"Ganglia in or about the walls of capillaries regulating their caliber."

"Spinal vaso-constrictor nerves running to muscles in the arterial walls."

"Spinal nerve fibers inhibiting the peripheral vascular ganglia, vaso-dilatory fibers."

"Inhibitory fibers from the skin to the vascular ganglia in their vicinity."

"Irritation of the skin can cause a dilatation of the capillaries through the inhibitory fibers, or contraction through the vaso-constrictor fibers."

"The vaso-motor and vaso-constrictor fibers emerge from the spinal cord through the spinal nerves. The vaso-motor fibers are united with a vaso-motor center in the brain, its extent being, in the rabbit, within a millimeter of the tubercula quadrigemina in the upper limit, and within four or five millimetres of the calamus scriptorius in its lower limit. From this center vaso-motor fibers arise and pass down the spinal cord and through spinal nerves and sympathetic ganglia to the various regions and parts of the body."

"The peripheral vaso-motor system, which keeps the capillaries and bloodvessels in a state of tonic contraction, is reinforced by the impulses coming from the brain vaso-motor center, and is in constant action."

"When a sensory nerve is stimulated, this center is thrown into increased activity, the bloodvessels in general contract, and, of course, increase the blood pressure in the arterial system, by the greater resistance to the passage of arterial blood into the venous system. There is also a vascular congestion of the region to which the irritated sensory nerve is distributed. This irritation paralyzes the peripheral vascular ganglia in the vicinity irritated."

There is also the sensory nerve of Cyon and Ludwig, which, when excited, inhibits the parts supplied to it and paralyzes the main vaso-motor center in the brain, and thus causes the whole capillary system to dilate and hence the blood pressure falls, there being less resistance to the passage of blood into the venous system. "Besides the vaso-motor center in the brain, there are others in the spinal cord which act."

I have quoted from Dr. Ott fully on the vaso-motor system because, although he has not to my knowledge experimented with chloroform, his valuable experiments, in general, have an important relation to and shed much light upon the subject we are considering.

When after death, in a chloroformed subject, the skin is cut, its substance is pale and bloodless. I have never lost a patient from chloroform, but often under the profound influence of this agent, I have seen the human patient pale and cold. Why is this? Is it not due in part to the nerve of Cyon and Ludwig being paralyzed? The capillaries of the skin cannot be contracted, for the heart and the great bloodvessels and the vessels in general are engorged with blood and relaxed. The vaso-constrictors are paralyzed by chloroform and permit the bloodvessels mainly in the abdomen to enlarge. Since we know that the final influence of chloroform is to paralyze, it cannot be that by its agency the vaso-dilators are stimulated to enlarge. The inhibitory fibers in the skin must be paralyzed also; so that there is only one class of these nerves, the vaso-constrictors, which being paralyzed, permit the dilatation of the heart and bloodvessels, as has been found in nearly every one of the cases reported in our experiments. The great fulness of the internal vessels and organs with blood would account for the paleness of the surface of the body, the blood having been drained away from the surface to the internal organs and vessels. This full state of the heart and bloodvessels is favorable to arrest of heart's motions, and while it is not probable that this effect is the cause of death, yet it is one of the factors in inducing it. Thus, I think that the paralysis of the excito-motor and inhibitory centers of the brain from chloroform will be assisted by the paralysis of the vaso-motor centers, and the consequent dilatation of the heart and great vessels.

But how are the lungs affected in chloroform anæsthesia pushed to death? The primary influence of this agent is to stimulate the lungs to increased acts of respiration and to increase the secretions of the mouth, throat, and salivary glands, and those of the bronchial mucous membrane Its secondary effects are to anæsthetize these surfaces, and, remotely, to paralyze the peripheral nerves of the lungs and lead to passive congestion of the bloodvessels of these organs. The vaso-excitors being also paralyzed, would also favor engorgement of the bloodvessels of these organs by their enlargement. At the same time that the lungs are locally affected by the chloroform and the vaso-motor paralysis, the excito-motor and inhibitory centers of the brain and medulla aid the vaso-motor paralysis in arresting respiration, and this affection of the brain and vaso-motor nerves is probably the reason why respiration ceases before the heart's action; and this statement, as to cause, is more likely true when it is remembered that the area of the lung surface is greater by far than that of the heart, and this will assist in casting a greater paralyzing influence upon the lungs, and lead more readily to their becoming first quiescent before the heart ceases to act.

I should here state that never in a single case of our experiments has a lung been found, before the chest was opened, that had not ample area for the maintenance of respiration, so that death here cannot, in my opinion, be due to apnœa. It is true that there is a partial apnœa due to the limited and congested area of the lungs, and this leads to a retardation of the pulmonary circulation, and, possibly, to some dilatation of the right heart.

But it remains to consider the influence of chloroform upon the brain in this death process. If the blood reaches the brain. during anæsthesia, containing chloroform as it does, it will permeate all parts of that organ. In the cerebrum unconsciousness is induced, in the cerebellum coördination is abolished, in the sensory ganglia sensation is lost, in the motiferous ganglia and tracts motion is wanting, and in the medulla the motor, and inhibitory, and vaso-excitor centers are all modified and paralyzed when death occurs. The spinal centers are also impaired in function, so that reflex motion is impaired. It would seem that when these centers of the medulla are so far paralyzed as to generate no more force, the lungs and then the heart cease to act, and the enfeebled state of heart and lungs, due to the local influence of the chloroform upon them, favors the final result due to paralysis of the medulla centers, and death follows. It must be remembered that the medulla is not congested, it is permeated with a chloformed blood acting as a paralyzing agent.

Under chloroform the subject hangs between life and death. Anæsthesia is all that is desired. To

accomplish this every organ and nerve center in the body is impressed, and yet how few die of this agent! Why? Simply because the influence of this anæsthetic is not pushed beyond insensibility, generally, and also there are usually no lesions of heart, lungs, or brain incompatible with such use of the agent. You will ask, why have deaths occurred suddenly from heart failure, which I believe is extremely rare without the lungs ceasing to act previously or simultaneously? I answer that there will be found a diseased heart, or a patient whose nervous system is so impressible as to lead to death, in the latter case by the dread and shock of the operation or from previous shock from other causes. Such examples are really nerve and brain deaths and cannot be strictly counted to chloroform mortality.

What are the particular changes induced in the medulla which arrest the transmission of motor force to the heart and lungs is unknown. I must state here that in my experiments again and again have I caused arrest of respiration and restored by artificial respiration, and accidentally have been able to do the same thing in the human subject. Once respiration is established the patient is restored, provided the heart has not ceased to beat. In the human subject I have in a number of cases encountered heart failures with arrest of respiration, but position of body, artificial respiration, and removal of chloroform effected restoration. Death from heart failure is then vastly the exception from this anæsthetic.

In restoring I have tried oxygen gas, electricity, artificial respiration, inversion of body, but all these fail when the heart has ceased to beat. Previously the patient's heart, lungs, and brain should be examined for lesions. Hypertrophy of heart is not incompatible with chloroforming, nor functional diseases of this organ with fair heart force. Atrophy and fatty degeneration of this organ contra-indicate its use.

Chronic alcoholic drinkers are dangerous persons for anæsthesia. Persons already insensitive from great shocks due to various injuries generally bear chloroform badly. I have seen this tried, and unless there is ample heart force this agent will depress. Persons with thready pulse from injuries bear this agent badly. Those with chronic organic diseases of lungs, as bronchitis, accompanied with free secretions in lungs are liable to give trouble during anæsthesia. Organic brain lesions require the most careful consideration ere this agent be used. Observation has taught me, as well as authority, that recumbency, as well as a free supply of air, is essential; that warmth of surface and extremities is important; also that the pulse, respiration, and iris (a dilated pupil should dictate caution at least) should be closely watched, and on the slightest failure the agent removed. When the cornea is insensitive, the insensibility point has been reached and the agent should be removed for a time. A moist and cold skin and extremities denote caution. Brandy, hypodermically, and artificial heat and sinapisms, and also electricity will aid artificial respiration.

I believe chloroform affects the secretions less than ether; but the latter is a safer anæsthetic than the former. I have seen cases that I could not etherize, as they would cease to inhale enough to anæsthetize. I would say care should be exercised in giving chloroform to old or feeble persons. Children and parturient patients bear chloroform well.

It occurs to me now that a medium-sized dose of strychnia given hypodermatically half an hour before the chloroforming would be a valuable safeguard by increasing the irritability of the nerve centers of the medulla and spinal cord. Morphine is said to increase the blood in the nerve centers, but it is a narcotic and it would hardly be proper to add this influence to the chloroform narcosis. Chloral has been advised, but it certainly favors heart failure and nervous exhaustion. Nitrite of amyl until the face flushes does good. A dependent position of the head is valuable, as it determines blood to the head. Small restorative hypodermatic injections of atropine are feasible. The fact that the respiratory and heart centers of the medulla are stimulated to action by carbonized blood is favorable, and may, to a limited extent, overcome the influence of the chloroformed blood circulating in these centers.

HUNTING THE GERM OF YELLOW FEVER.

By FRANK S. BILLINGS, M.D.,

(Director of the Patho-Biological Laboratory of the State University of Nebraska.)

[Continued from page 127.]

SOME of these objects color well, in sections, in Loeffler's methylen-blue and caustic potash (1:10,000) solution, but when very sparsely represented, or when the sections are the least bit thick, this method will leave one in doubt in regard to yellow fever material.

The only reliable and, if properly used, invariably successful method by which these organisms can be made visible, even in quite thick sections and when only few are present, is by using the well-known carbol-fuchsin solution so commonly used in "hunting" the tubercle bacillus, and here, too, we use heat, but very much more than is necessary, to fix the color in B. tuberculosis. But,

1. Wash the sections to be colored for a few moments in some absolutely germ-free caustic potash solution (1:10,000).

2. Place these in salt-cellar containing two-thirds caustic potash solution (1:10,000) and one-third carbol-fuchsin (5 per cent. carbolic acid in distilled water, 100 parts; alcohol, 95 per cent., 10 parts; fuchsin 1 part, filter; and also filter each time on using) and place over slow flame until vapors arise, and one-half the coloring material has been evaporated. The slower the better.

3. Wash in 1 per cent. acetic acid, *in alcohol.*

4. Wash in distilled water to remove surplus and any sediment. Experience only can show how much color to remove.

5. For five minutes in ol. terebinth $\frac{2}{3}$, alcohol $\frac{1}{3}$.

6. For five minutes in pure ol. terebinth.

7. For five minutes in xylol.

8. Oil of cloves, and mount in balsam.

Notwithstanding every endeavor on my part, it was

absolutely impossible for me to procure any material of any kind whatsoever from the various outbreaks of yellow fever in our Southern States during the summer and fall of 1888.

Monopoly in original research on questions pertaining to public health or national economy seems to be a new phase of the high-protection policy in this tax-beridden country. However, another was more fortunate, and his wonderful results have been heralded to the world in the following resonant praises:

"DR. REEVES' DISCOVERY."

From the Chattanooga Times—A clipping sent without date.—"Dr. Sternberg, of Baltimore, Md., who has for the last six or eight years been investigating the yellow fever, with a view to discovering the specific cause, it will be remembered spent a portion of the summer at Decatur investigating the disease. While in Decatur he kindly sent to Dr. James E. Reeves, of this city, pieces from the liver and kidneys of several cases of yellow fever for microscopic examination with a view of seeking for the specific germ of that disease. Dr. Reeves took these tissues and began his investigations. From a mounting of the very first cases he found a microörganism in them, which led him strongly to believe that he had found the germ. He continued his research and thoroughly examined all of the tissues sent him from Decatur, and he found the same thing in all, more or less developed. He forwarded mounted slides to various microscopists and scientific men throughout the country, who, one and all, say that the result is exceedingly interesting, if nothing else, some declaring that it was the yellow fever germ. Mounted slides of these tissues were sent to Prof. H. J. Detmers, of the Ohio State University. These slides were photographed and forwarded to the Johns Hopkins University. The microorganism is a bacillus, rod-like in shape, and is found in schools of millions in the tissues. So very much struck are the scientific men with the discovery that Dr. Reeves has been invited to come to Johns Hopkins University, under pay, to make a demonstration of what he has found and the method employed. In accordance with this invitation, Dr. Reeves will leave for Baltimore the latter part of the first week of the new year. A *Times* reporter called to see Dr. Reeves and asked him with reference to his discovery. The Doctor was not prepared to say definitely what his find amounted to, but said: 'The discovery of these bacilli in the tissues leads me to hope that I have found the germ of yellow fever, but as a matter of course we cannot say definitely until we have further carried on investigation. I can say this much, that in all my experience with microörganisms I have never seen anything like that which I have discovered in the tissues furnished me from yellow fever patients who died at Decatur. I have examined these tissues in every way and under different staining agents, and have always met with the same result, which leads me to believe that whether these bacilli are the specific germs of yellow fever, they are certainly an organism pertaining to and only found in the tissues of persons suffering from yellow fever. I shall go to Baltimore and consult with scientific men of Johns Hopkins University and my experiments will be carried out, and we may then be able to tell what it is I have found, but until these precautions have been taken by making experiments as peculiar to yellow fever cases, there is, of course, more or less uncertainty about it.'

The reporter was shown by the doctor the mountings he had made from the various tissues and saw a most interesting sight. The tissues were filled with rod-like spots, hundreds of which might be put upon a blunt pin-point."

It will be seen that Dr. Reeves said: "The discovery of these bacilli in the tissues leads me to hope that I have found the germ of yellow fever." . . . "I can say this much, that in all my experience with microörganisms, I have never seen anything like that which I have discovered in the tissues furnished me from yellow fever patients who died at Decatur."

The last assertion is unequivocally false!

Why, if Dr. Reeves is such a noted scientist, have we not somewhere a description of that microorganism, the like of which he had never seen before?

Why have we never had a report of that much vaunted trip for consultation with the celebrities at Johns Hopkins University?

The fact is that Dr. Reeves knew he had seen an abundance of just such organisms (microscopically) in tissues which came from cattle diseased with the Southern cattle plagues, and which he stained for me in 1887.

The fact is that Dr. Reeves had in his possession my report on "The Southern Cattle Plague and Yellow Fever," with a description and illustration of the very organism he saw, months before he ever saw it in tissue from Decatur, but he could have seen it in the Lacerda material which I sent him had he so desired, though he is very careful not to mention either.

Perhaps Dr. Reeves can account for these things. His work would have been really valuable, as confirming testimony, had he published it, as he should have done, and not used it as an advertisement to peddle slides.

It will be seen that Dr. Reeves speaks of "yellow fever patients," using the plural number and of the "tissues furnished" from these patients, but what is of more value, he says: "*I have examined these tissues in every way and under different staining agents and always met with the same result.*" No one will more cheerfully admit than I that as a mere technicist and manipulator of microscopic sections, Dr. Reeves has but few equals and no superiors in this country, if in any. I am no such delicate worker, for time is too precious with me to give any pains to appearances. Here it is results only, no matter how one gets at them, and with a very sincere disrespect for rule-of-three methods. Naturally, on seeing such wonderful reports from Dr. Reeves, I was very anxious to acquire one of his specimens, and was fortunate enough to obtain one selected by himself, as especially suitable for photographing. This slide is distinguished by an epauletts on each end—not the

plain labels of ordinary workers, but the more elaborate affairs emanating principally from manufacturers and dealers in model slides. Upon one of the epauletts may be read "Dr. Jas. E. Reeves, Microscopical Laboratory, Chattanooga, Tenn." and upon the other, "Yellow Fever, Liver, .$\frac{6}{5}\frac{6}{2}$'."

When I received this slide it was colored in "Bismarck brown," and as the liver cells were very full of a glancing granulous detritus, it was only with the utmost difficulty that one could isolate the much more minute germs of yellow fever, but by careful focusing they could be occasionally picked out between the cells. I am writing on April 24, but received this slide January 2, 1889. From that time until April 20 I preserved it as it originally came to me, in order to show it to visitors that they might compare it with my own made from the various materials herein mentioned. No one has had any difficulty in seeing that apparently the same organism was in all of them. Desiring to have a better idea of the actual numerical representation present, I most carefully removed the coverglass and specimen and dissolved all the balsam, and recolored it according to the fuchsin method previously given. It can be truly said and actually demonstrated that the number of ovoid belted germs present is greater in this specimen than in either of the others examined, and that by this method they can be so distinctly seen as not to allow of the possibility of their being mistaken for detritus granules "mast-zellen," or anything else.

Let us now review this evidence a little. There seems to be no reason to doubt the genuineness of the material. Of that from Brazil Lacerdo has told us that:

"In all these preparations (from six persons),[1] *without exception, I have found one bacterium exactly identical with that which Babes has already found in material sent him from here by me.*"

Now, Babes described and illustrated that organism so well that when we are assured likewise that the material sent from Havana by so accomplished a practitioner (and one holding such an important position as "Inspector of the United States Marine Hospital Service"), as Dr. Burgess, is all from "undoubted cases of yellow fever," it would be carrying skepticism to the verge of imbecility to doubt that it is one and the same germ.

To be sure Babes failed in finding it in some other material examined later, and Sternberg only found it in "two out of nine cases" of which he brought material from Brazil, perhaps the very same, and Gibier did not succeed in finding it at all, but, on the other hand, as said above, Lacerdo reports finding it "in all preparations without exception," and here we have the same organism also "*in all preparations without exception*" from "six *undoubted cases*" *from Havana, and again reported by Dr. Reeves*, whose accuracy of observation and delicacy of technique I personally know can be depended on, and who says of it: "*I have examined these tissues from yellow fever patients in every way, and with different staining agents, and have always met with the same result.*"

Now, we do not know just how many persons the material examined by Dr. Reeves represented, but we do know that in all these tissues no one has spoken of the presence of any other organism, and any one with a grain of pathological acumen must say, *that under such circumstances the organism present must have been the cause of the disease with which the individuals were diseased from whom the material in question was taken.*

What then was that disease?

Has not every observer who collected this material, even to Dr. Sternberg, asserted, without equivocation, *that it was all from "undoubted cases of yellow fever?*"

This being so, *then I unhesitatingly pronounce the germ present in all these cases to be unquestionably the etiological element in the yellow fever, and that failure to demonstrate its presence in all such cases, as well as by cultures by those having the opportunity, is due to technical inability in most cases, though accidental failure must be allowed for in a few.*

I am perfectly well aware of the extreme relish with which my estimable confréres in the world would "jump on" any serious error in the work of so severe a polemic as myself, but I am equally well aware of the character of the few abilities I may possess and of the painful exactness used when it is absolutely necessary. Some may think me over bold, but where caution is warranted by the evidence I can use as much of it as any one. What scientific investigators are seeking, must seek, is the exact facts, and no matter who makes an error, the more severe the exposé of the same the better for the world at large, and I certainly not only do not fear but have so acted in my course as an investigator as to court all the criticism that can possibly be thrown against my work. Thus far the errors exposed have been made manifest by their extreme rarity. In fact, so rare have they been that not one error of fact has thus far been found in my published work except one of misconception, which I exposed myself in a late publication.

Let us now return to Sternberg's address for a moment. It has been noted already that he said:[2] "In my researches by the method of staining thin sections of tissues hardened in alcohol, I have encountered several different microörganisms, but no one of these has been found in a series of cases."

[To be continued.]

THE BANDAGE IN CARDIAC DROPSY.—O'Donnell (N. Y. *Med. Jour.*), reports the following case: Mitral insufficiency, dilatation of the right heart, general dropsy, hemoptysis, cough, jaundice, and anæmia. Urine scanty and bloody. Pulse rapid, feeble, and irregular. Great dyspnœa. He was given tonics, the scrotum tapped, and a bandage applied tightly to the legs and arms.

The heart became more regular, and the patient improved so much that he has been able to superintend his farm, the bandage still remaining in position.

The use of an elastic bandage would have been still better in this case, for several reasons.

HYSTERECTOMY FOR LARGE FIBRO-MYOMA.

By D. BENJAMIN, M.D.,
Surgeon, Cooper Hospital, Camden, N. J.

H. M., aged thirty, living in the southern part of the State, came to me on March 24, 1888, suffering from a large abdominal tumor, which she stated her physicians called an ovarian tumor. I obtained the following history: Her mother died of erysipelas, one sister died with cerebro-spinal meningitis. Patient's past condition was stated to have been moderately healthy until last summer, when she commenced to lose flesh; at this time there was noticed a slight enlargement of the abdomen, which was attributed to dropsy.

In October, 1887, she was examined by a physician who stated that there was a tumor in the left ovarian region, then about the size of a fist. Two months afterwards she was subjected to another examination, and the tumor was found to have increased in size to that of a child's head. No history of any injury to this region could be obtained. Her menstrual flow had been regular, sometimes profuse, had missed one month, which she attributed to a cold.

She began to suffer from vomiting and constipation, and occasional abdominal pains, these symptoms had constantly grown worse, until almost every meal was vomited, and constipation became more and more obstinate, so that powerful purgatives had to be administered, but were losing their effect, and symptoms of obstruction were becoming marked.

She had lost fifty pounds in weight within a few months, but as she had been previously inclined to embonpoint, her emaciation was not extreme on palpation through the abdominal wall. The tumor appeared symmetrical and mobile, did not feel so hard as is common with fibroid tumors, nor so soft as a cyst, was not nodular, felt very much like a pregnant womb in the early part of the ninth month. Fluctuation could not be positively demonstrated. Percussion-sound dull, except a small area in each flank.

Vaginal examination showed cervix drawn up, and enlargement in Douglas's pouch about the size of a retroverted womb. Rectal touch gave no additional information, flexible urethral sound passed into os uteri about two inches, taking a forward direction. Pregnancy having been eliminated by the examination, a diagnosis of solid or semi-solid tumor involving womb could be made; but the exact relation of the ovaries to this tumor was not clear, and exploratory incision was advised, with a view of ascertaining the exact relation of the tumor to the pelvic organs, and the possibility of its removal, with the understanding that any beneficial operation that would seem feasible should be proceeded with. Accordingly, on March 29, patient was etherized, the usual incision was made in median line, and surface of tumor exposed. Tumor was quite elastic, and of a dark muscular flesh color, and wedged so tightly in the superior strait of the pelvis, that only one ovary could be reached (the left which was enlarged). Adhesion being slight, the incision was extended upward, with scissors, sufficiently to enable the upper part of the tumor to be reached, which was free, but in contact with the stomach and liver.

The incision was then extended upward and downward sufficiently to enable the tumor to be delivered forward through the abdominal incision.

Both ovaries and Fallopian tubes could then be easily reached, while the large tumor was held upward, out of the abdominal cavity, by an assistant. The pedicle could not, at this stage, be thoroughly examined. The right ovary was found crowded down into Douglas's pouch, and was enlarged to about the size of a hen's egg, and roughened on the surface.

The right Fallopian tube was also much enlarged, the left was about double the normal size, and adherent. Both ovaries and both Fallopian tubes were carefully ligated and cut away. The exact relation of the base of the tumor to the womb could now be clearly made out, and it was apparent that room enough could be made above the insertion of the vaginal wall into the cervix to remove the tumor and body of the womb (which was thoroughly uniformly fused) without necessarily wounding ureters, bladder, or other pelvic organ. I then determined to remove the entire tumor and womb, since to return it to the abdominal cavity would have been to leave her in almost as bad a condition as before the operation, with respect to the obstruction and other difficulties which the tumor caused, and at the same time be little less dangerous to the patient's life than complete hysterectomy. I then carried the incision downward as closely to the pelvic bone as the bladder would permit, ligated each of the round ligaments in two places, and cut between, applied Koeberle's clamp and cut away the tumor. The stump was at least three inches in diameter. Tumor was about thirty inches in circumference. After all bleeding points had been properly secured, and all clots removed from the abdominal cavity, the bowels and peritoneum were thoroughly washed by pouring three or four gallon pitcherfuls of warm water into her.

The omentum, which had been lying on a towel, was returned and arranged over the bowels. The pedicle was fixed in the lower angle of the womb, and incision closed with silk sutures at intervals of less than half inch. Wound was dressed antiseptically, and patient placed in bed.

Temperature which had been normal previously to the operation was taken three-quarters of an hour afterwards, and found to be $97\frac{1}{5}$, at 4 P.M., $100\frac{4}{5}$. The second day at 7 P.M. it reached $100\frac{2}{5}$, pulse 128, breathing 28. Third day, 7 A.M., temperature 101, 7 P.M., temperature $101\frac{2}{5}$, pulse 116, breathing 24. Fourth day, 7 A.M., temperature $99\frac{2}{5}$, 7 P.M. $100\frac{3}{5}$. Fifth day, 7 A.M., temperature $99\frac{2}{5}$, catheterization stopped on account of cystic irritation. Patient constantly improved without any untoward symptoms, and was discharged in six weeks after the operation. Clamp came off on the twenty-third day. Has not vomited since the operation. Has had no pain. All functions are normal. States that it is the first time she has felt well for four or five years. Has returned to her home in the country, with rosy cheeks, full of

life, and at this date, May, 1889, is in perfect health. Has not been sick a day since the operation, and is glad that she parted with her womb and ovaries.

In determining the value of the operation of hysterectomy to humanity, it is important that all cases should be reported, as I found the literature on the subject so meagre at the time of the above operation, that reliable data could not be obtained in this country. The operation has never, so far as I can learn, been performed in New Jersey, but as hysterectomies are becoming more frequent and successful, ample statistics will soon be forthcoming.

Hospital Notes.

PHILADELPHIA HOSPITAL.

SYPHILITIC RUPIA.

MAN broken down in health, and presents a history of having a chancre seven months ago. One month ago he had a manifestation of it on his body. At the present time he has two large syphilitic rupia on the anterior part of his leg, and several others on his forehead. Will dress the rupia with ung. hydrarg. and ung. zinci oxidi. Tonics of iron, quinine, and strychnine were given. Will begin with hydrarg. prot-iodide, gr. 1/6, ter die, and will increase the dose to tolerance. Will be given in pill form for three years. Will also give potassium iodide, gr. x after meals. Good food and out-door exercise. If, after three years and a half, no manifestations of syphilis exist, he will be permitted to marry, and will have good, healthy children.—*Ransley.*

REMOVAL OF A CICATRIX.

This man has a horrible cicatrix on the posterior portion of his thigh, the result of a burn. It causes him pain when he sits down or attempts to walk. The man was etherized and the cicatricial tissue dissected out and the parts dressed with iodoform. It will be treated as an ulcer, and transplantation of skin will be made in a few days. Limb will also be placed on a splint, and absolute rest and quiet maintained.—*Ransley.*

UNIVERSITY HOSPITAL.

OVARIAN TUMOR.

DR. GOODELL removed a very large ovarian tumor which contained several gallons of fluid. There were some slight adhesions. The other ovary was removed, and it was shown that a cyst was forming on the side of it. Wound was dressed antiseptically. In concluding the operation he spoke of after treatment. No nourishment will be given by the mouth for twenty-four hours; no opium unless absolutely necessary, and then by the hypodermic. Beef tea and whiskey with milk, per rectum, if necessary. On the second day after the operation she will be given a tablespoonful of milk and a cup of tea, and every three hours, if it agrees, two tablespoonfuls of milk will be given; and so slowly increased, and if she is feeling good other nourishment should be given.

MEDICO-CHIRURGICAL COLLEGE.

LUPUS VULGARIS.

SHOEMAKER, in enforcing the importance of differential diagnosis, contrasted such diseases as epithelioma, lupus vulgaris, and syphilis, calling attention to the important fact, that whilst epithelioma was painful, lupus vulgaris was painless.

Removal by the knife or otherwise is the treatment for the first, but operative interference in lupus vulgaris is not advisable. In advanced cases complete healing of the lesion is not attempted, as the disease, if driven from the surface, attacks some one of the viscera, preferably the lungs.

Lupus vulgaris commences on the nose or cheek; is characterized by extreme redness, especially in advanced cases; a gradual spreading, by tubercular breaking down of the skin, the tubercles being gelatinous, and the formation of cicatricial tissue in the center as the disease spreads. In the treatment for lupus vulgaris he gives tonics, cod-liver oil, etc., and applies, at times, carbolic acid to the surface. Recently galvanism is being used.

FOR PSORIASIS.

For psoriasis and pemphigus he administers the arsenite of sodium, hypodermatically, giving one-half of a grain at a dose, and repeating three or four times each week.

In a majority of such cases arsenic makes no impression on the system, in medicinal doses, when given by the mouth.

If the little syringe is objected to, give the drug by suppository.

OLD SYPHILIS.

For old syphilitic cases he uses the bichloride of mercury in the same manner, and in all his practice he has never seen any bad results following the use of the hypodermic syringe. Care and cleanliness are the rule.

ACNE ROSACEA.

For acne rosacea in the first stage he ordered oleate of bismuth; for the second stage, oleate of lead; and for the third, electrolysis, using not over ten cells, with the positive or indifferent electrode placed on the back of the neck, and the negative needle to the enlarged capillary, inserted at right angles with the enlarged vessel.

Caution is urged even in such minor operations with the needle not to carry the electrolysis too far and produce a slough.

DEGENERATED HEARTS.

Woodbury stated that in a large number of cases of death by accident, of persons presumably healthy, nearly every heart was found to be fatty or otherwise degenerated.

SPASMODIC CROUP.

Spasmodic croup is sometimes caused by over-feeding, and milk too rich in casein causes vomiting in over-feeding.

NEARLY A SPECIFIC.

Tincture of nux vomica is almost a specific for the nervousness of drunkards.

WHAT IS DISEASE?

Disease, from the standpoint of the patient, consists in feeling an ability to do or not to do work. The physician looks at physiological and functional action or derangement.

FOR CHANCRE.

Garretson's treatment for chancre is to destroy it with London paste (caustic soda and quick lime), which never causes inflammation or gives pain. It will slough a wart in a few minutes. He removes enlarged tonsils with this agent in preference to the surgical operation, but never uses it on the tongue.

He recently sloughed out a large carbuncle with the paste in a comparatively short time.

EXCISION OF THE UVULA.

After excising an elongated uvula, he gives the patient gum Arabic to dissolve in the mouth; it tends to coat the raw surface. Erysipelas may follow excision of the uvula.

A MOUTH WASH.

As a stimulating mouth wash, either for spongy gums or in the after treatment of operations in the oral cavity, he prefers the tinctures of myrrh and capsicum, āā, adding just sufficient of the mixture to water to render the latter milky.

AN INJECTION.

In injecting the urethra for gonorrhœa he directs the patient to compress the urethra as far back as possible, so as freely to distend the canal and allow full action of the remedy.

As abortive treatment, he considers the injecting of a solution of chloral hydrate as nearer a specific than any other known remedy.

TOUCHING THE URETHRA.

Pancoast stimulates the erectile function, when absent or defective, by "touching" the more sensitive parts of the urethra some forty or fifty times by successive rapid twistings of the bougie as it is being slowly withdrawn.

EMACIATION.

This is a lady, aged thirty-four years. She is a widow, who has never borne children. She has always been delicate, but has had no disease which has any connection with her present condition. For a number of years she has been steadily declining in health, but without any discoverable cause. She has no disease of the heart, kidneys, or liver. Her lungs are free from any deposit which would give rise to dulness; she has never had a cough, but the resonance is somewhat greater than normal, yet there is no bulging of the intercostal spaces or other indication of emphysema. It is likely that the bronchi are somewhat dilated, yet there is no secretion to decompose and cause ulceration or fibrosis. In fact, the bronchiectasis is probably secondary, as well as the sinking in of the intercostal spaces, both being due to her emaciation. It is of this which I wish specially to speak. It is carried to a singular degree. There seems to be no fat remaining on her body. The skin is smooth and fair, not wrinkled or sallow, but every bone can be distinctly seen through it from the absence of the subcutaneous investment of fat. Examing her rectum, it gives to the finger the sensation of a fully expanded membrane, distended to its full extent; a thin membrane from which mucous glands, muscular tissue, and submucous and interspacial fat have disappeared. The vagina is in the same condition. The womb is larger than normal, the os lacerated deeply, and the lobes into which the fissures divide it are everted, hard, rounded masses. Hard nodules are also to be felt in the body of the womb. This reads like cancer, but the decline has been progressing for at least ten years, and the nodules have been two years developing to their present size, while there is no leucorrhœa, hydrorrhœa, hemorrhage, or pain. If this be cancer it is a most unusual course which it is taking. Her digestion is very weak, and the number of things she "can't eat" is very great. On account of the condition of the rectum she suffers from a peculiar form of constipation, as she feels the contents of her bowels reach a certain point, whence she has no power to dislodge them, especially as her rectal mucous membrane is quite dry. Her pulse, respiration, and temperature are normal. She is so weak that during menstruation she is compelled to remain in bed.

The history excludes the tubercular and cancerous affections, Bright's disease, and the various organic affections. It is not an essential anæmia, as the only recognized form of this runs a shorter course. Judging by the symptoms, we would say that the disease is a general atrophy of the fatty tissues, with the supervention of an as yet obscure disease of the uterus, probably fibroid.

In the treatment of this lady we have rung the changes on the tonics. She cannot take strychnine, as it aggravates an irritability of the bladder which she has at all times. The only remedies we have obtained any benefit from are *hydroleine* and cascara sagrada. Hydroleine is the only preparation of oil she can retain. Cascara keeps her bowels regular better than any other laxative, whether given in maltine or in the form of cascara cordial. At present we are trying to introduce another fat into her body, by rubbing her skin with lanoline and applying it to the vagina on cotton tampons.—*Waugh.*

THE PROPER ANÆSTHETIC.—J. W. Silk, M.D. (*Journal of Laryngology and Rhinology*), summarizes as follows an article on the Choice of Anæsthetics in Naso-pharyngeal Operations:

1. That the possibility of using nitrous oxide should always be considered in naso-pharyngeal operations of short duration.

2. Failing this, the advantages and disadvantages of ether, and by preference, of the combined method, should be carefully weighed before deciding the question.

3. That chloroform, though so frequently used, has, over and above the objections made to it upon general grounds, drawbacks special to these particular operations, and when employed its use should, especially in prolonged operations, be limited to the primary induction of narcosis, substituting ether a as early a stage as possible.

The Times and Register

A Weekly Journal of Medicine and Surgery.

New York and Philadelphia, June 15, 1889.

WILLIAM F. WAUGH, A.M., M.D., Editor.

REPRESENTING THE

COMMENTS.

ALL sorts of comments, commendatory, critical, pessimistic and ill-natured, have been made upon our new journalistic scheme. For the first we owe our brethren due thanks, and will bear their courtesy in mind. For the criticisms, we are equally grateful. As to the pessimists, we have to say that in our peregrinations through the world, we have found mankind composed of two varieties; one consisting of those who sit down and demonstrate the impossibility of doing a thing; the other of those who get to work and do it. Even if failure should follow upon any individual effort, the world is at any rate a gainer that the effort has been made. The great orators were all failures. Demosthenes and Cicero were unable to prevent the loss of their countries' liberties and fell victims to their patriotism. Burke failed in his greatest effort; Webster and Clay failed to settle the slavery question. But did these men live in vain? Is the world better to-day for their labors, or for the inglorious acquiescence of their compatriots who submitted without a struggle?

But in our case, the result is simply a question of arithmetic. It is not a difficult calculation to ascertain that by combining the financial and intellectual capital of several journals into one, a better, stronger, and in everyway more satisfactory journal can be produced than any one of its members alone. You can find twenty medical journals which do not contain in all as much material of value as the London *Lancet*. And yet the twenty journals would cost the subscriber $30.00 instead of $7.50. Its 15,000 subscribers and seventy-two pages of advertising enable the *British Medical Journal* to give its readers seventy-two pages weekly of brevier print; and to pay the best men in England to contribute to its pages. Its editors are paid well for their work. How many of our American journals earn enough to repay their editors for the time and labor expended on them?

It is somewhat singular that this movement, which is calculated to secure an adequate recompense to those men, should be misrepresented into a "Trust." We say to the editor, Put the same energy into our weekly which you are now giving your monthly, which doesn't pay its expenses, and instead of paying for the privilege of being an editor, you will receive such a recompense as will enable you to do better work than you have ever done previously. Because you are relieved from financial worry, and can devote your leisure to some worthier work than correcting proof, beating sense into the heads of printers, etc.

To the subscriber we say: Our journal represents the combined efforts of a large number of workers; men who have been editors and contributors to medical journals previously. We will spare no expense or pains to secure the best material for your use, and believe we can give you the worth of your money. The Journal is independent, not controlled by any publishing house, manufacturing firm, college or clique. It is devoted to the interests of the medical practitioner. We will be glad to hear of anything which will make a weekly medical journal more useful to you, and, whenever practicable, will incorporate such suggested features in our Journal.

To the advertiser our message has already been given: We will give good service at a reasonable price. Our circulation is given frankly, and if any one desires further proof, we are perfectly willing to furnish it.

It is true that some of our contemporaries will suffer by our effort to put medical journalism upon a sound basis, it is the survival of the fittest, and nobody has any right to complain. If we have a larger and more valuable circulation than other journals, the advertisers will drop them and come to us; if we are able to pay higher prices for material and thus get the best, and print a larger number of pages for the same subscription price, the subscribers will take our journal in preference to theirs. But is there any reason to complain of this? If a man wants to buy, he has the right to buy in the cheapest market. Anyone who finds fault with this, and raises the specious cry of "Trust," simply confesses his own inability to compete with a competitor who conducts his business on business principles. There is no menace to honest journalism in this, but an endeavor to raise an American medical publication to the highest standard, by combined effort.

HYSTERIA.

IN a lecture delivered at St. Bartholomew's (*Lancet*), Dr. J. Matthews Duncan gave utterance to some of that sound, practical common-sense which is characteristic of the best English teachers when at their best. He remarks that in dealing with hysteria the process of cure is to a great extent one of education. While a patient with an endless string of complaints may be quickly cured by a pessary which is not needed, by an electrical application or by any new fad, or be forced or shamed into good habits, yet

the physician should never stoop to such unworthy methods of treatment. Sometimes you will lose your patient if you do your duty, and such a loss is to be welcomed. Be kind, wise and firm, direct and simple. This is the most successful plan. It involves no untruth or deception, and cures ten times as many as the roundabout plans.

This is sound advice as far as it goes; but it constitutes only the text, and requires the sermon to elucidate it. The most important element in the successful management of a case of hysteria is undoubtedly the attaining of an ascendency over the mind of the patient. When she has learned to lean with perfect confidence upon her doctor, when she obeys his directions implicitly and unquestioningly conforms her life to his precepts, the cure is well under way. But let the physician beware! It is so essentially consonant with the relations of the sexes that the patient will love the man who has assumed such a relation to her, that this complication is to be expected. And experience has proved over and over again, that the proudest masculine intellects are most apt to succumb to the arts of just such weak, ailing, unintellectual women. To successfully cope with the difficulties of such a situation demands a strength of moral principle which is not always found in combination with the sympathetic disposition which wins the confidence of such patients.

It is with such cases especially that we have reason to deplore the extinction of that ancient species, the family physician. That the present is an age of progress, we cannot doubt, when we see miladi go to the oculist, the aurist, the laryngologist, etc., etc., her fair body requiring the services of a dozen specialists to keep in order the various parts of its complicated mechanism. But we sadly miss the old doctor who brought her into the world; who knew her grandparents, and whose wise advice is constantly needed in the training of the young brood. Even if his therapeutics were confined to "quinine, hydrarg. mit. and potas. nit.," the young miss who needed a spanking instead of a pessary, a merry romp in the open air instead of syr. hypophos. comp., less study instead of potas. brom., was better off under his eye than she is to-day.

The difficulties in the treatment of hysterical women have apparently been solved by the Weir Mitchell system. Certainly it relieves the physician of danger and provides the most effectual method of subduing the morbid impulses which lead to hysterical manifestations. Deprived of unhealthy surroundings and in the power of the master, beyond the reach of friends' interference, the problem is shorn of its greatest difficulties. But, is the cure permanent? Can this or any other thing change the ingrained selfishness of a nature? Where the disease is the result of improper education and the habit of selfishness has been fostered by unwise parents, and confirmed by self-indulgence, there is hope that a true change of heart, a radical cure, may be effected. But there are some natures so utterly unregenerable, that one longs for the law of Inquirendo Island, by which these cases could be formally condemned as "non compos;" and projected into the sea, once for all.

Annotations.

A TRIBUTE.

UNHAPPILY, the grievous pages of history attest beyond all doubt the truth of that melancholy saying: "Man's inhumanity to man makes countless millions mourn;" but when we reflect on the beautiful promptitude with which those unscathed by the late disasters have responded to the needs of the suffering, and the bounteous charity that has come, as freely as come the gifts of Heaven, not only from our own people, but also from strangers in distant lands, then we ask whether we may not offset this ugly aphorism by saying with willing and truthful lips that: "Man's great humanity to man makes countless hearts rejoice."

WOMEN AS INVALIDS.

MANY women who suffer from anæmia, general weakness, or from any of the long list of "female complaints," accept their lot with a certain amount of resignation, since they consider these misfortunes as part of the heritage of their sex. Perhaps such belief is acquired and fostered by the continual reference to woman as the "weaker vessel," the "weaker sex," and so on; but is this belief well founded? We think not. The physical condition of the woman of the present day is poor, simply because the absurd demands of fashion and of society force her into an unnatural existence, the one in the way of habits; the other of dress. The exploits of female gymnasts and the labor done by the lower class women in many parts of Europe prove that, *cæteris paribus*, woman is as capable of physical exertion as is man. Girls in the unconventional days of childhood are usually as healthy as their boy companions, but at about the age of thirteen or fourteen the vigorous sports begin to be considered unladylike, and are exchanged for a sedate saunter, an hour's crocheting, or an interesting novel. In short, she ceases to attend to her physical needs. And then the dress. What is it possible for her to do in the tight, stiff casings of modern dress?

It was found necessary in Russia to prohibit men from fastening their trousers to their hips by a band, so much trouble was caused by the constriction. How much more trouble should and does come from the continuous wearing of the corset. Woman's dress has been a hygienic reproach for many a year, and probably will remain so for a long time to come; yet the only way to bring about the much-needed reform in dress and habits is to keep the subject constantly alive. Fortunately, the beneficial effects of such agitation are already seen, both in the approach to a more rational costume and in the modern tendency for women to take part in active and healthy sports.

BOOK INFECTION.

THE *Am. Analyst* in commenting on this dangerous source of infection, cites several cases in which disease was evidently contracted through handling a book formerly perused by a scarlet fever patient. When we consider the number of circulating libraries, and the freedom and carelessness with which books are given out and taken back, we are reminded that there is here an important field for investigation and precautionary measures.

OUR MEDICAL COLLEGES.

A VALUABLE leader in the *American Journal Medical Association* on this subject shows a lamentable state of affairs. A table is given which illustrates the requirements of the different colleges of the United States and Canada. In the course of his article the writer says: "It is shown that medical education in this country is in a heterogeneous state. We have colleges for the uneducated and for the educated student; colleges for the would-be doctor fresh from the plow-handle; colleges in which the pupil may patch up his educational defects—to the satisfaction of himself and the faculty; and from this class up through a series of gradations to the college that requires the matriculant to have the general education without which no one is ready to study medicine. We have colleges from which a student may be graduated without having seen a patient except over the rail of the amphitheater; from which the pupil may receive a diploma—a license to practice in many States—without being able to make the simplest urinary analysis, without having seen a case of labor, without having received instruction in applying the simplest surgical dressing or bandage, without the ability to recognize normal tissue under the microscope, or by the naked eye, without the ability to make a postmortem examination. It is gratifying to know, however, that this class includes but a small number of colleges."

THE reports concerning the health of Johnstown are contradictory. There is an evident conflict between the reportorial desire to write up something sensational, and the fact that there is as yet but little sickness beyond that which is incident to exposure, injury and mental distress. That the elements for a serious outbreak of some pestilential disease are to be found there is certain; and if this danger is averted the credit is to be given to the efficient work of General Hastings and the Pennsylvania Board of Health. The General has proved himself a born leader of men; one of those whose true worth is revealed only by such an emergency as the present. Dr. Lee has also shown himself to be the right man for his responsible position. Governor Beaver has taken a responsibility from which a weaker man would have shrank, in issuing $1,000,000 from the State Treasury for the purpose of restoring Johnstown to a habitable condition. But there is small danger that the people will not enthusiastically ratify his action, or that the public spirited citizens who, headed by Mayor Fitler, pledged their private means to back the Governor in his action, will be called upon to pay the bill. Altogether, Pennsylvania has good reason to be proud of the display of executive ability shown by her Administration at the present time. The State which produced a Meade and a Hancock, and the sturdy fellows who held the lines against Pickett's charging Virginians, has plenty of the same material still, waiting the emergency which demands its employment.

Society Notes.

THE ILLINOIS STATE MEDICAL SOCIETY.

PROCEEDINGS of the thirty-ninth annual meeting, held in Jacksonville, May 21, 22, and 23.

First Day. Morning Session.

The Society was called to order by the President, Charles Warrington Earle, M.D., of Chicago, and some regular routine business accomplished.

First Day. Afternoon Session.

Dr. Kreider said that during the past few years much had been written about

the mortality of pneumonia.

Men whose experience has extended over a long period of years affirm that the death-rate is much higher under the present accepted modes of treatment than it was forty years ago, when the pathology of this disease was almost unknown. He advanced the following conclusions:

1. That baths should only be given in those cases which are not progressing favorably.

2. In severe cases nothing is calculated to give so much relief to all bad symptoms.

3. Rules for selecting cases and administering baths cannot be rigidly given. The thermometer is not always a guide for their administration. Difficulty of respiration and lack of secretion should lead to their employment regardless of the height of the mercury.

4. The bath should be given at a temperature of 100° or less, depending on the severity of the case and the condition of the patient. Baths of extremely low temperature have not been found necessary as yet, but I should not hesitate to employ them if occasion should require.

5. Stimulants should be given just before entering and on coming out of the bath tub. The patient should not exert himself in the least.

6. The physician should himself superintend and aid in giving the bath. This rule can only be broken by having trained nurses who are competent to meet emergencies which might arise.

7. The bath treatment is capable of shortening the duration of the disease and convalescence, and of reducing mortality. Liebermeister says it has been reduced in his hands from 25 to 10 per cent. The ice coil will be found effective in the milder cases in reducing temperature and relieving pain, if placed directly on the affected side.

The paper was discussed by Drs. Carter, Miller, Barritt, Herriott, Townsend, Earle, Thackery, Kreider, Prince, Baxter, McArther, Cook, Lee, Hurst.

Dr. Townsend, in the course of his remarks, said that as regards the matter of temperature, there is much irregularity. Cases are on record where the temperature has reached 125°, which, in his opinion, were due to hysteria.

The President thought that if the statement of the last speaker were true—viz., that a temperature had been reached of 125° in the case of some patients of the central part of the State, it would make physicians from the North feel a little dizzy.

Dr. Kreider said the statement made by Dr. Townsend was absolutely correct, and could be found in Sagand's work, entitled, "Thermometric Observations." It could also be found in Wagner's "Pathology," a reprint from Sagand's book.

Dr. A. J. Baxter, of Astoria, read a paper on

DYSPEPSIA.

Dr. N. S. Davis, of Chicago, said he knew of a great many conditions of the digestive organs that go under the general designation of dyspepsia, but they were as diverse from one another as hot water is from an ice pack. The only success he has in treating such cases is to analyze each case on its merits, and if he finds out the habits and pathological condition of the digestive organs and rationally adjusts his treatment accordingly, he finds generally but little difficulty in curing them.

The paper was further discussed by Dr. A. Wetmore, of Waterloo.

Dr. J. L. White, of Bloomington, read a paper entitled,

HYGIENE AND DOCTORS' FEES

which was discussed by Drs. Kreider, Davis, G. L. Eyster, of Rock Island, and closed by Dr. White.

Second Day. Morning Session.

The report of the committee on

DISEASES OF CHILDREN,

was made by Dr. A. T. Darrah, of Bloomington.

Under the general term of *summer complaint*, a very unscientific but common term, is grouped such diseases as diarrhœa, dysentery, cholera infantum, entero-colitis. Of the great mortality of children under the age of five years, vital statistics show that a large percentage is caused by bowel diseases during the hot weather. This is especially marked in the larger cities of the central and Southern parts of the United States. Philadelphia may be taken as an example. Here the mortuary records show that deaths from these causes are at a minimum during the months of December and January, and that during the months of July and August the maximum death-rate is reached.

Heat weakens by destroying the cohesive force between atoms. The result is a relaxed and flabby condition of the tissues. Continuous high temperature, acting upon the very delicate nervous organization of children has the effect of either destroying the digestive ferment of the stomach, otherwise its natural secretion is arrested, normal digestion ceases and the abnormal condition of fermentation may take its place. Heat being the prime factor in the causation, and acting through the sympathetic nervous system, we should counteract its effects, hence *cold* is the remedy. By reducing the temperature the cause of the disease is removed. We should not wait for the little ones, during warm weather, to become sick, but begin the use of tepid bathing, cool or cold water. Use it freely, and let it be of a temperature suited to each individual case. If these suggestions were acted upon, and a more liberal use of the remedies at hand employed, the lives of many children would be saved.

Dr. A. E. Hoadley, of Chicago, said after an experience of twelve years in treating diarrhœa in infants, he could speak of the utility of the treatment advocated by Dr. Darrah. In his practice he teaches families to keep the babies cool, and they do it in this way: Just as soon as they begin to feel the effects of heat, faces red and head tossing about, crying, etc., instead of giving them extra food of some kind, part of their clothing is removed; if it is excessively hot they take off more. The children are then wiped down with tepid water, and allowed to lie on the floor naked, if sufficiently hot, and there they may remain all day. Towards evening, when the weather becomes cool, their clothing is put on. With this line of treatment the children had no diarrhœa, indigestion, or any trouble during the summer. He is rarely called to see a case of acute diarrhœa in infants during the summer.

Dr. Robinson, of Wyanet, called attention to the fact that many parents refused children water to drink when they have diarrhœa. He advocates giving them all the water they can possibly drink.

Dr. Baxter said the diet was of as much importance as medicine in the treatment.

The treatment was further discussed by Dr. Davis, at great length.

Dr. W. T. Thackeray, of Chicago, presented his report as chairman of the committee on

DRUGS AND MEDICINES.

He said among the most important introductions during the year is that of Prof. Pribram, of Berlin, viz., *agaricine*.

A paper entitled

NOTES ON THE CAUSES AND MANAGEMENT OF HERNIA IN INFANTS AND YOUNG CHILDREN

by Dr. K. Miller, of Lincoln, was read by Dr. Leeds in the absence of the author.

The next thing in order was a paper on

VAGINAL HYSTERECTOMY

by H. T. Byford, of Chicago, which was read by Dr. F. H. Martin, in the former's absence.

Dr. Byford commences by saying that one of the greatest and most astonishing of the many triumphs of modern gynecological surgery is the development of vaginal hysterectomy. The death-rate of recent vaginal hysterectomies is about 10 per cent., while that of some operators is even lower and steadily decreasing.

Dr. C. Truesdale, of Rock Island, read a paper on the

ETIOLOGY AND PATHOLOGY OF UTERINE DISPLACEMENTS.

He summarized his remarks as follows:

1. The normal typical position of the uterus in the pelvis in an erect position of the body, instead of being upright, is nearly horizontal.

2. Anteversions of the uterus so-called, pathologically, have no existence.

3. The body of the uterus is supported by the bladder, the bladder upon the vagina, the vagina upon the perineal septum as far back as the rectum, the neck suspended by the utero-sacral ligaments on a plane as high as the body with the empty bladder.

4. All ordinary displacements, such as prolapsus, anteflexion, retroversion, and retroflexion, are produced by contracture of the muscular walls of the vagina.

Dr. Franklin H. Martin, of Chicago, read a paper in which he reported three cases of

FIBROID TUMORS OF THE UTERUS

operated upon by Apostoli's method, which illustrated the three different procedures of the method, viz.:

1. Intra-uterine galvano-caustic, positive operation.

2. Intra-uterine-galvano-caustic, negative operation.

3. The intra-vaginal galvano-puncture operation.

He also gave a short summary of results obtained by himself in a series of one hundred consecutive cases treated by Apostoli's method, which were as follows:

1. Of the hemorrhagic cases, 95 per cent. were cured of hemorrhage.

2. Tumors entirely disappeared in 8 per cent.

3. Tumors were reduced in size in 78 per cent.

4. Tumors not affected in size either from failure of treatment, or from patients discontinuing treatment, or for other reasons, 14 per cent.

5. Neuralgic and other pains relieved in 90 per cent.

6. No deaths.

7. Symptomatic cures, 68 per cent. (these 68 not including the 8 actual cures).

Dr. L. L. McArthur, of Chicago, read a paper on

UTERO-VAGINAL FISTULA, AND TREATMENT, WITH REPORT OF A CASE.

He emphasized some points in the technique of the operation, as follows:

1. Suturing in the longitudinal rather than in the transverse diameter of the vagina, because there is less contraction on the stitches and greater facility in introducing them.

2. Choice of sutures varies with many, though silk-worm gut has, perhaps, the preference, Sims, Bozeman, and Hegar preferring silver wire. Pippingsjeld claims excellent results from the use of alternate silver and iron wire, believing that the galvanic current thus induced plays an important part in the union. Excellent results are on record with silk as the suture.

3. Simon, who, perhaps, did more than any other operator to simplify the treatment, demonstrated that it was neither necessary to retain a catheter in the bladder after operation, nor to maintain the reclining posture. He permits his patients to rise as soon as they feel disposed, simply requiring them to empty the bladder, at least every two hours.

4. Render the urine aseptic by some such agent as saccharin, benzoic acid, or boracic acid internally.

5. That if the first operation succeeds in locating the orifice of the fistula on the mucous surface of the bladder, that constitutes one step of some operators methods, who then at a later sitting close the bladder opening.

6. That any colored liquid may be used to differentiate the fistula, as those above mentioned.

7. It is not necessary to put off the cure until the age of puberty is reached.

8. Encircle the orifice of the fistula with about one-quarter inch of m. m. This serves to retain the ureter in the bladder and prevents by a valve-like action the escape of urine through the wound.

9. That the sphincter vesicæ in a congenital case has never been trained to its proper function and may need attention in the line of internal medication.

SECOND DAY. AFTERNOON SESSION.

Dr. O. B. Will, of Peoria, Chairman of the Committee on

OBSTETRICS,

presented his report.

Wisdom, says Dr. Peak, should teach us that chloroform should be used in all cases of labor where not contra-indicated by

1. Organic diseases of the brain.

2. Destructive lesions in the lungs.

3. Fatty degeneration of the heart.

4. Extreme general anæmia.

Dr. Will closed his remarks with the following suggestions:

(*a*) When the proper time arrives keep the head in constant contact with the perineum, in the intervals of pain, with the hand or the forceps, as the case may be.

(*b*) Keep the parts in view so that the condition may be always known.

(*c*) Whenever possible cause the head to pass the outlet during the intervals between pains.

Dr. Abbey F. Rooney, of Quincy, contributed a paper entitled

THE USE OF THE CURETTE IN PUERPERAL ENDOMETRITIS.

Whenever there is fever or pain or fetor, which points to this cause, the quickest and the surest way to abort the trouble is to carefully remove, with a dull curette, every easily detachable fragment. There need be no violence, and there should be no fear of consequences.

A Vienna physician had reported 200 cases in which he had curetted for puerperal endometritis, with no deaths. She had never heard of such records following the use of the uterine douch.

Dr. Chas. C. Hunt, of Dixon, read a paper entitled

CARBOLIC ACID, PURE OR IN CONCENTRATED SOLUTION, AS A DISINFECTANT IN THE TREATMENT OF PUERPERAL SEPTICÆMIA,

in which he said the following cardinal points are now generally admitted:

1. Puerperal septicæmia is of bacterial origin.

2. It is identical with surgical fever, but under exaggerated conditions.

3. It is preëminently infectious.

4. It is preventable.

During the spring of 1838, he had seen a great many interesting cases. He would limit what he had to say exclusively to the claims of carbolic acid, either undiluted or in very strong solution, as a local application to the points through which diseased germs find their way into the system—namely, the lesions in the genital tract, and the interior of the uterus.

His clinical experience with undiluted or very strong solutions of carbolic acid tends to establish:

1. That it is not attended with danger.

2. That if applied early, the temperature is immediately reduced.

3. That it is efficient as a disinfectant; no microorganisms or spores can exist or develop where it touches.

4. That to apply it effectually and safely, we must be guided by the sense of sight as well as that of touch.

SECOND DAY—EVENING SESSION.

DR. ROSA H. ENGERT, of Chicago, read a paper on the

RELATION OF UTERINE FIBRO-MYOMATA TO THE ORGANIZATION OF THROMBI.

DR. N. S. DAVIS presented a report on

METEOROLOGICAL CONDITIONS AND THEIR RELATION TO THE PREVALENCE OF ACUTE DISEASES,

which was followed by *impromptu* remarks on the subject of

WRITER'S CRAMP,

by DR. D. R. BROWER, of Chicago, during which he exhibited an appliance devised by Nussbaum.

THIRD DAY—MORNING SESSION.

DR. EDMUND ANDREWS, of Chicago, read a paper entitled

ONE HUNDRED OPERATIONS FOR STONE IN THE BLADDER.

He said the object of the paper is to compare the safety of litholapaxy with that of lithotrity and of lithotomy, so far as his own practice is concerned. He had operated for stone over one hundred times, employing all the different methods in vogue.

The following is a summary of results: Litholapaxy (Bigelow's operation), cases 40; deaths, 1; mortality, 2½ per cent. Lithotrity (after Sir Henry Thompson's method), cases 6; deaths, 1; mortality, 17 per cent. Lithotomy below age of puberty, cases 55; deaths, 7; mortality, 13 per cent. Lithotomy above age of puberty, cases, 29; deaths, 5; mortality, 17 per cent.

In respect to the old form of lithotrity his experience of one death in six operations is substantially like that of other surgeons Litholapaxy can generally be performed only in adults. If we take the published statistics of adult lithotomy over the whole globe, amounting to some 4000 cases, the average mortality varies from 12 to 18 per cent., while litholapaxy in Chicago—at least in his practice, 40 cases had a death-rate of only 2½ per cent. The most remarkable success claimed for lithotomy comes from the warmer regions of Asia, where calculi seem to be very abundant.

The following are gathered from authentic sources: Baboo Ram Norain Das Bahadore, of India, cases, 284; deaths, 17; mortality, 7 per cent. Dr. Kerr, American Hospital, China, cases 187; deaths, 19; mortality, 10 per cent. Dr. Nishman, Altoungan, Amasia, Asia Minor (educated at the American Mission), cases, 265; deaths, 5; mortality, 2 per cent. Dr. Sewny, of Lives, Asia Minor, cases, 40; deaths, 1; mortality, 2½ per cent. Total number of cases, 740; deaths, 42; mortality, 6 per cent.

DR. A. E. HOADLEY, of Chicago, read a paper on

TUBERCULAR JOINT DISEASE.

DR. H. H. STARKEY, of Chicago, made the report of the Committee on

OPHTHALMOLOGY AND OTOLOGY.

He directed attention to the advisability of having the eyes examined in every case of persistent headache not relieved by the ordinary medical means, even when the eyes are not obviously at fault.

DR. GALEZOWSKY called attention to the close relation between some eye troubles and irritation of the upper teeth.

The only new drug that seems to have met with any special favor is the antiseptic creolin.

DR. ISADORE BERMANN recommends the use of lactic acid in from 10 to 30 per cent. solution for cases of chronic suppurative otitis that have resisted all other treatment.

DR. LYMAN WARE, of Chicago, read a paper on

SYPHILITIC CYCLITIS,

and reported several cases.

Officers for 1890.—President, Dr. John Wright, of Clinton. First Vice-President, Dr. J. P. Mathews, of Collinsville. Second Vice-President, Dr. T. H. Cullimore, of Jacksonville. Permanent Secretary, Dr. W. Graham, of Chicago. Assistant Secretary, Dr. Lyman Ware, of Chicago. Treasurer, Dr. Thomas M. McIlvaine, of Peoria.

The Society adjourned to meet in Chicago in May, 1890.

CONSERVATIVE TREATMENT.—A. B. Judson, M.D. (N. Y. *Med. Record*), makes a plea for more conservative methods in the treatment of the joint diseases of children.

SALT LAKE CITY.—H. D. Niles, M.D. (N. Y. *Med. Record*), calls attention to the sanitary advantages of Salt Lake City as a health resort. He tabulates as follows the advantages he enlarges upon:

1. A distinctly local climate, apparently possessing to a marked degree the popular requirements of a high-altitude resort.

2. Unexcelled salt-water bathing, the peculiarities of which may indicate unusual remedial virtues.

3. Hot, warm, and cold sulphur springs, of alleged marvellous curative properties.

Book Reviews.

A Contribution to the Study of Friedreich's Ataxia, with Exhibition of Cases. By J. P. Crozer Griffith, M.D. Reprinted from the Transactions of the College of Physicians of Philadelphia. February 1, 1889. 8vo., pp. 80, paper.

Excessive Venery, Masturbation and Continence. By Joseph W. Howe, M.D. New York: E. B. Treat. Price, $2.75.

The impression made by this book is not a favorable one. There are too many details of a kind to render it unsuited to the young; while for physicians there is little which has not already been well said by others. The prescriptions are models of polypharmacy.

Oeuvres Complètes. De J. M. Charcot, Maladies des Poumons et du Système Vasculaire. Tome V, avec 51 figures dans le texte et 2 planches. Paris: Aux Bureaux du Progrès Médical. 8vo., pp. 640. Price, 15 francs.

"This volume contains the lectures, memoirs, and observations of M. Charcot on diseases of the lungs, blood, heart and vessels," brought together in one volume. The papers which appeared many years ago, have been carefully edited so as to give the present status of medical opinion.

Physiological Notes on Primary Education and the Study of Language. By Mary Putnam Jacobi, M.D. New York and London: G. P. Putnam's Sons, 1889. 12mo., pp. 120, muslin.

The first two chapters are entitled, "An experiment in Primary Education." The third, "The Flower or the Leaf," is an answer to Miss Youmans' criticism upon the preceding. In the fourth, entitled "The Place for the Study of Language in a Curriculum or Education," the author defends the study of Latin, and proposes a natural method of teaching a child the languages in general.

Errors of Refraction. By F. Valk, M.D. New York City: G. P. Putnam's, Sons. 1889.

This book is composed of a series of lectures which Dr. Valk delivered at the New York Post-Graduate School. It is a well written and very practical book. It goes carefully but simply over the field of which it treats; describing the anatomy and refraction of the eye with emmetropia (normal refraction) before taking up the errors or rather defects of refraction; as hypermetropia and myopia, with astigmatism and muscular asthenopia, as well as presbyopia. He describes the ophthalmoscope and its use in examining the eye and detecting and calculating defects in refraction, etc. But we cannot agree with him in saying that Loring's ophthalmoscope is undoubtedly the best refractive instrument. It is true that it is a good instrument in its way, but there are some of later date and design that far excel it as one for the examination and instruction of defects in refraction. The book is well illustrated, and being an excellent synopsis of the subject is well worthy the attention of students and physicians.

The Functions and Disorders of the Reproductive Organs; in Childhood, Youth, Adult Age, and Advanced Life, considered in their Physiological, Social, and Moral Relations. By William Acton, M.R.C.S. Seventh Edition. Philadelphia: P. Blakiston, Son & Co.

If one had a son who had arrived at the age when it is right and proper that he should be taught something of the physiology of the reproductive organs, this is the book to put in his hands. It is plainly written, so that it can be readily understood; the subject is delicately yet truthfully handled, and the elevated morality inculcated is what a youth should be imbued with.

Jahresbericht ueber die Fortschritte auf dem Gebiet der Geburtshilfe und Gynækologie. Edited by Prof. Dr. Richard Frommel. Co-editors: Drs. Ahlfield (Marburg); Bumm (Wuerzburg); Frommel (Erlangen); Hofmeier (Wuerzburg); Lochlein (Giessen); Saenger (Leipzig); Schwarz (Halle); Stumpf (Munich); Veit (Berlin); Wyder (Zurich). First Annual volume, being the report for the year 1887. Published by J. F. Bergmann, Wiesbaden. 1888.

This book of 555 pages octavo, as indicated by its title, is the first annual report on progress in the domain of obstetrics and gynecology. It contains, as far as this is possible, a complete bibliography pertaining to all subjects, general and in detail, related remotely or directly, to the science and art of obstetrics and gynecology as treated of by the authors of every civilized nation, together with a short and succinct criticism of the work of each. As such it constitutes a veritable "multum in parvo," each particular of which is easily accessible by means of the well arranged index of subjects, preceded by a complete alphabetical list of authors' names.

Part I, obstetrics, besides a review of works on the general and historical aspects of the subject, on didactic works and text-books, and reports of public and private clinics, contains brief résumés on the anatomy of the female pelvis and sexual organs; their evolution and development; the physiology and pathology of ovulation, menstruation, impregnation, gestation, parturition, the lying-in period, lactation; obstetric therapeutics — general, medicinal, mechanical and surgical; and closes with a short consideration on forensic obstetrics.

Part II, gynecology, likewise first pays attention to the general and historical; to text-books, instruments, electricity, methods of examination and investigation, etc., and then procedes to consider the pathology of the uterus, ligaments and tubes; the vagina and vulva; the ovaries; the urinary organs; the general, medical and surgical therapeutics, and closes with a brief reference to the physiology and pathology of menstruation.

It will thus be seen that the work is of great value not only to the individual practitioner, general or special, or to the teacher and student; but—and especially if followed annually by a book of similar scope and character—of historical worth to the medical profession at large and as a whole, as forming so many connecting links in the onward progress of the science and art of obstetrics and gynecology.

RECHERCHES CLINIQUES ET THERAPEUTIQUES SUR L'EPILEPSIE, L'HYSTÉRIE ET L'IDIOTIE. Par Bourneville, Médecin de Bicètre, Sollier, Pilliet, Raoult, Internes du Service, et le Dr. Bricon, Conservateur du Musée. Vol. VIII, avec 27 figures dans le texte. Paris: Aux Bureaux du Progrès Médical, 1888. Pp. 263, paper.

In this volume we have a report of the clinical service for epileptics, idiots and backward children at the Bicètre during the year 1887. Illustrations are given of the articles used in the school, which resemble those used in kindergartens. The first part is mainly statistical. In the second, the clinical section, procursive epilepsy occupies one hundred and sixty pages, and twenty-six contain an account of two cases of double athetosis with imbecility. Dr. Bourneville treats of the central temperature in epilepsy. The fourth chapter is upon anomalies of the genital organs in idiots and epileptics; the fifth, malformations in imbeciles; the sixth, of cystico-colic epiploon; the seventh, of a case of asphyxia by strangulation; the eighth, of the dentition of idiots and imbeciles; the ninth, insanity of adolescence, and onanism.

IMMUNITY THROUGH LEUCOMAINES. By EUSEBIO GÜELL BACIGAHIPI. Translated from the second French Edition by R. F. Rafael, M.D. New York: J. H. Vail & Co. 1889.

This, a most interesting little work, is written in the terse, almost epigrammatic style, characteristic of much of the French writing at the present time. Mr. Güell treats of the important subject of immunity from microbic diseases not from the standpoint of experimentation, but from that of logic. He claims to have discovered a law that will explain both the known facts with regard to immunity from certain diseases and the results gained by bacteriologists.

He uses the term leucomaines in a very general sense, namely, "intending to designate by it the totality or a part of the products of elimination which are the result of the vital functions of any microörganism."

His theory is briefly, that the products of microbic life (leucomaines) are themselves inimical to the further existence of these microörganisms; and that, taking smallpox for an example, one who has had that disease is afterwards rendered proof against it, not by reason of the fact that there has been exhausted from the patient's body a certain pabulum on which these special microbes feed, but that the leucomaines left by them are hostile to their existence.

This theory also explains crises in diseases. The crisis is the moment at which the leucomaines have accumulated in amount sufficient to put a stop to further increase of the microbes. This is the turning point. If the microbes have been checked while yet the patient has enough vital material on which to exist, he will live; but if not, he succumbs.

The author's theory is supported by many citations from eminent bacteriologists, is of great simplicity and of general application, and seems to us the most plausible explanation that has yet appeared.

THE TIMES AND REGISTER. Subscribe now; $3.00 per annum.

Pamphlets.

Report of Morse Dispensary of Cooper Medical College, San Francisco, Cal., 1888.

Tenth Annual Announcement of the Indiana Eclectic Medical College, 1889–90.

Transactions of the American Dermatological Association, Washington, September, 1888.

Clinical Observations on the Action of Phenacetine-Bayer. By Dujardin-Beaumetz, and others.

Seventy-second Annual Report of the Managers of the Friends' Asylum for the Insane, Philadelphia.

Diseases of the Skin associated with Disorders of the Female Sexual Organs, by George H. Rohé, M.D., Baltimore, Md., Prof. of Dermatology and Hygeine in the College of Physicians and Surgeons, etc. Reprint from the *Buffalo Medical and Surgical Journal*, February, 1889, 13 pages.

In his paper the writer has collected many of the scattered observations on record which tend to demonstrate an existant relationship between the sexual disorders and some cutaneous eruptions. A complete classification of these is presented, together with a brief description of each, and the plan of treatment found to act most satisfactorily in the various conditions.

New Form of Posterior Colporrhaphy, by J. H. Kellogg, M.D., of Battle Creek, Mich. Reprint from the *Boston Medical and Surgical Journal*, 6 pages.

Though numerous operations for the relief of procidentia uteri have been suggested, none have yet been found to completely answer the required purpose. The improvements suggested by Dr. Kellogg are rational, and though not as yet thoroughly tested, bid fair to give most satisfactory results. Much of his success, he claims, is due to the use of the buried suture for approximating the deep surfaces of the wound.

Pressure Forceps *vs.* the Ligature and the Suture in Vaginal Hysterectomy, by F. C. Dudley, M.D., Chicago. Reprint from Vol., XIII, Gynecological Transactions, 1888, 16 pages.

The rapidly diminished mortality rate which has followed the various improvements suggested within the last decade in the operation for total extirpation of the uterus, is a strong incentive to the adoption of other means which shall still further enhance the prospects of recovery after this grave surgical procedure. Dr. Dudley strongly urges in the operation for vaginal hysterectomy the substitution of the hemostatic forceps for the ligature, claiming that by their use not only is the time of the operation considerably lessened, but that hemostasis is more prompt and reliable, the sloughing stump more quickly removed, and drainage more effectively secured. He predicts from their employment a reduction of the mortality in carefully selected cases to four or five per cent., or less.

The Histology and Surgical Treatment of Uterine Myoma. By Henry O. Marcy, A.M., M.D., LL.D., of Boston. Reprinted from the "Transactions of the Ninth International Medical Congress, Vol. II. 14 pages.

This most interesting problem in abdominal surgery has commanded the attention of eminent surgeons the world over, all of whom have united in their efforts to arrive at a satisfactory solution to the question. Dr. Marcy has considered the subject in a comprehensive manner, especially dwelling upon the histological development and factorage of the growth. As the result of his investigations he asserts that the character of the growth consists mainly in an excessive development of muscular bundles, while the connective tissue rarely, if ever, becomes a prominent factor. In discussing the surgical treatment of the condition where the tumor has not reached any considerable size, he unites with Tait, Battey and others in recommending the removal of the uterine appendages in order to arrest further development, while in cases of excessive growth he advises hysterectomy with intraperitoneal treatment of the stump as in ovariotomy.

Gleanings.

HEMOSTATIC COLLODION (Paresi).—

℞.—Collodium . . . . . 100 parts.
Phenic acid . . . . . 10 "
Tannin (pure),
Benzoic acid . . . . . āā 5 " —M.
Sig.—Apply with brush.

—*Revue de Thérapeutique.*

ALOPECIA (Steego).—

℞.—Cacao butter . . . . . 16 gram.
Olive oil . . . . . 8 "
Tannin . . . . . 3 "
Quinine . . . . . 0 gr. 10
Spirit of sylvius . . . . . 3 " —M.
Sig.—For friction.

—*Revue de Thérapeutique.*

ARTIFICIAL CARLSBAD SALT (Ziemssen).—

℞.—Sulphate of sodium . . . . . 40 gram.
Carbonate of sodium . . . . . 6 "
Chlorate of sodium . . . . . 1 "

Dissolve in hot water, evaporate and reduce to powder the salt which remains. Dose: half a teaspoonful in hot water.

—*Revue de Thérapeutique.*

ANTISEPTIC DENTIFRICE (Dujardin-Beaumetz).—

℞.—Acid phenic 19.00
Acid boric 25.00
Thymol 0.50
Essence of mint . . . . . 20 drops.
Tinct. of anis 10.00
Water . . . . . 1 litre.—M.
Sig.—To be half diluted with water.

—*Bulletin de Thérapeutique.*

FOR TYMPANITES AND CONSTIPATION.—

℞.—Naphthol,
Carbonate of magnesia,
Powdered charcoal . . . . . āā 5 gram.
Essence of mint . . . . . 11 drops.
M. make fifteen powders.
Sig.—One before each meal.

—*Gazette de Gynécologie.*

INJECTIONS FOR OBSTINATE LEUCORRHŒA (Monin).—

℞.—Infusion of chamomile . . . . . 500 gram.
Alum . . . . . 10 "
Iodide of potassium . . . . . 4 "
Tinct. of iodine . . . . . 2 " —M.
Sig.—Three injections daily.

—*Gazette de Gynécologie.*

ANOTHER SYMPTOM OF PREGNANCY (Parganime).—This new symptom which shows itself at an early period of pregnancy is the pulsation of one of the uterine arteries. The exploring finger should be passed around the inferior segment of the uterus near the internal orifice, while the palmar surface of the other hand is carried over the uterus and allowed to remain several seconds in position over the different points of circumference to be analyzed. When this symptom is found in a healthy adult woman it means that conception has taken place.—*Gazette de Gynécologie.*

PERFUMED CHLOROFORM. — In cases when this anæsthetic causes nausea and vomiting or when it is badly tolerated, Prof. Nussbaum recommends the employment of chloroform perfumed with the oil of cloves. In no case in which this has been used has any accident occurred.—*Revue de Thérapeutique.*

THE MEATUS URINARIUS.—J. C. Olmstead, M.D. (Atlanta *Medical and Surgical Jour.*), writes an able plea for the meatus urinarius, in which he objects to the slitting of that important orifice unless for the most cogent reasons, on the ground that the patient is subject to lifelong discomfort as a result of this little operation.

TREATMENT OF CHRONIC ECZEMA OF THE VULVA IN YOUNG GIRLS.—

1. A solution of phenic acid (2 per 100) is to be applied over the surface three times daily.
2. The parts affected are to be touched lightly with ordinary acetic acid once a week.
3. If ulcerations should exist from scratching, the following powder should be applied:

℞.—Iodoform . . . . . 5 gram.
Alum . . . . . 10 "

—*Gazette de Gynécologie.*

SMALLPOX.—Baudon has treated a number of cases of confluent smallpox by the following method with uniformly good results:

1. The entire body is covered three times daily with the following pomade:

℞.—Salicylic acid . . . . . 10 gram.
Vaseline . . . . . 225 "

2. Powder subsequently with,

℞.—Acid salicylic . . . . . 10 gram.
Magnesia . . . . . 250 "

3. Twenty-five centigrammes of sulphate of quinine three times daily.
4. A solution of boric acid for gargarisms.
5. Milk at discretion.—*Bulletin de Thérapeutique.*

A SPECIFIC FOR CATARACT.—The juice of cineraria maritima acted in the case of Dr. Mercer like a charm. After being operated on the right eye for cataract, six years ago, without good results, his left eye also was affected with the same disease, and total blindness ensued. He was then advised to use the juice of this plant, which is held in high repute by the natives of Trinidad, and he began the instillation of one or two drops in each eye three times a day.

The results manifested themselves very soon. After a few weeks he was able to see, and could tell the time from his watch. After four weeks the improvement was very marked, and at the present time he is able to count the fingers and see them with the right eye, which had been operated without result. All this happened in the short time of about two months.

The drug does not cause irritation, except a little smarting sensation, which lasts a few minutes, and is followed by a profuse flow of tears. The juice of the ripe leaves is better and stronger in its action than the young leaves, but they are very hard to obtain. At present preparations are being made to acclimatize the plant in England.—*Med. Fress.*

PHENACETINE.—T. W. Ayres, M.D. (N. Y. *Med. Record*), highly praises phenacetin as an antipyretic. He gives from eight to ten grains as often as necessary, to control the temperature, having given as much as sixty grains in nine hours without bad result.

NEW DRUGS IN THROAT DISEASES.—Kenneth Millican (*Laryng. and Rhinol*) praises *æsculus hippocastanum*, common horse chestnut, gtt. iij of tincture, every three hours, in granular pharyngitis, early stage; tincture of arnica, gtt. j–iij, in muscular fatigue of throat, and bichromate of potash in chronic laryngeal and pharyngeal catarrh.

VACCINATION AS A TREATMENT FOR PERTUSSIS.—Dr. Pesa Cheratino reports two cases of pertussis cured in a short time by vaccination. He obtained his idea from Jenner, who had noticed that children vaccinated but for a short time resisted the malady, and that a primary vaccination in a person suffering from the disease not only diminished the intensity but also the duration of the same.—*Union Médicale.*

FOR A COLD.—T. G. Davis, M.D. (*College and Clinical Record*), says that he has success with the following combination, which for greater elegancy he has had put in triturate form by H. R. Mulford & Co., of Philadelphia:

℞.—Tinct. aconiti rad . . . . . ♏ 1-5
Tinct. bryoniæ . . . . . ♏ 1-10
Tinct. belladonnæ . . . . . ♏ 1.10

If quinsy or tonsilitis threatens he can usually abort it by alternating with the above carbonate, gr. $\frac{1}{100}$, every two hours, and a gargle of borax in hot water.

ANAMOLIES IN THE GENITAL ORGANS OF IODIOTS AND EPILEPTICS.—Bourneville gives the following conclusions as the result of his observations at Bicètre:

1. Idiots and epileptics very frequently present these anomalies in comparison with healthy persons.

2. Those who have only become epileptic at a certain age, after partial development has taken place, present these anamolies much less frequently than idiots. Their genesic aptitude also appears to be unhappily less impaired than with the latter, if one may judge by the smaller proportion of cryptorchids.

3. Atrophy of the testicle occurs almost as frequently on the right side as on the left.

4. The physical and intellectual degeneracy produced by epilepsy seems to have a real influence upon the production of varicocele, which non-epileptic idiots never have.

5. When epilepsy attends the infant from birth it causes in all its being an arrest much more marked than when the disease begins at a later period; and this is most strongly manifested in the genital organs.

6. Idiots, epileptic or not, frequently present a special form of the penis, called the bell-clapper or clubbed form. This form is not due to masturbation, certain subjects presenting it never having practised onanism.

A NEW ARTIFICIAL LEG.—A. S. Hudson, M.D. (Boston *Med. and Surg. Jour.*), advocates a new style of artificial leg, one in wnich the stump fits much as the leg does in an ordinary boot; the weight is thus distributed over the whole surface of the enclosed member, and not on the end of the stump.

PHYSICIANS should never lose sight of the fact that in obscure cases simulating arsenical poisoning, there may really be such poisoning, gotten from wall paper, printed goods, labels, and the like.

An article in the *Medical Press and Circular* calls attention to the fact that not only is more than a safe amount of arsenic frequently found in wall papers, but that it is also found in dress stuffs such as cretonnes and muslins. A patient who made a number of curtains out of certain cretonne was afflicted a few days afterwards by boils, which broke out on her arms and face. One of the cretonnes examined by a chemist yielded 19½ grains of arsenious acid to the square yard. The writer appended this list of articles in which arsenic has from time to time been found:

Paper, fancy and surface, colored: In sheets—for covering cardboard boxes, labels of all kinds, advertisement cards, playing cards, wrappers and cases for sweetmeats, cosaques, etc., the ornamentation of children's toys, covering children's and other books, lamp shades; paper-hangings for walls and other purposes, artificial leaves and flowers, wax ornaments for Christmas trees and other purposes, printed or woven fabrics intended for use as garments; printed or woven fabrics intended for use as curtains or coverings for furniture, children's toys, particularly inflated India-rubber balls with dry color inside, painted India-rubber dolls, stands and rockers of rocking-horses, and the like, glass balls (hollow), distemper color for decorative purposes, oil paint color for decorative purposes, lithographic color printing, decorated tin plates, including painted labels used by butchers and others to advertise the price of provisions, Japanned goods generally, venetian and other blinds, American or leather cloth, printed table baizes, carpets, floorcloth, linoleum, book cloth, and fancy bindings.

DIGESTIVE FERMENTS IN THE INTESTINAL DISORDERS. — It seems somewhat strange, with our present knowledge of digestive ferments, that the application of pancreatin and pepsin in the diarrhœas and intestinal disordrs of children, especially those arising from inanition, is not more general.

The use of these products in such diseases would save the lives of many little ones, otherwise doomed.

No practitioner, possessed of a modicum of therapeutic and physiological knowledge, will admit that chalk mixtures, opiates, astingents, etc., meet fairly the indications in these cases. The ant-acids act merely mechanically, soothing the irritated mucous membranes; opiates are dangerous to nurslings, and uncertain, for it is impossible to gauge their use so as to attain the exact limit essential to intestinal anæsthesia and arrest of peristaltic action, without narcosis; and astringents, while repressing secretion, at the same time retain and favor the absorption of ptomaines and other poisonous products which have

provoked the flux—they limit the dejections at the expense of non-elimination of the toxic agents.

In such cases, and in all those of enfeebled digestion, in which the food remains undigested and fermenting in the stomach and intestines, pepsin and pancretin and peptonized foods, afford us pure and simple physiological remedies, whose administration is attended with no dangers; and their employment does not preclude the use of cathartics, or of agents anti-toxic to ptomaines.

The best results have been obtained from such treatment, though it must be admitted in cases of unusual gravity, when collapse threatens, that coto and wild yam are sometimes of value to check the flux, the digestive ferment following to secure proper digestion and nutrition. So long ago as 1856, Joulin and Corvisart (*Rev. Med. Chir. de Paris*) outlined this mode of treatment, and claimed the happiest results therefrom; and more recently it was advocated by Trousseau and Pidoux, Barthez and Rilliet of Francee, and Ellis and Davidson, of the United Kingdom. Later still, Dr. J. Milner Fothergill ("Handbook of Practice," p. 40) remarks of pepsin: "Its utility in the treatment of imperfect digestion, and diarrhœa in children, is certain." Prof. J. Lewis Smith (Prof. Dis. Children, Bellevue Hosp. Med. Coll.; *Archiv. Pædiatrics*, 1886, p. 518) expresses exactly the same opinion. Frof. Frederick John Farre (*Pareiras Mat. Med. and Therap.*, p. 943) commends pepsin "*very highly in cholera infantum and summer complaints of children.*" And Bartholow declares (*Mat. Med. and Therap.*, p. 68): "Very great success has been attained in the treatment of the *diarrhœa of infants* by pepsin. . . . The motions will be quickly changed in character, and the nutrition of the child improved by giving it immediately after each supply of food." He further recommends (Naphey's *Medical Therapeutics*, p. 395) the employment of peptonized milk or milk gruel for food in these cases, in which he is supported by Wilson Fox ("Diseases of Children," II, p 821), who considers "pepsin invaluable in gastralgia and all irritative states of intestinal and stomach mucous membranes."

With such evidence, and with the physiological knowledge that at present obtains, it is evident the digestive ferments are too little studied or employed. Yet we must admit there have been good grounds for such neglect, in that the pepsins upon the market, for the most part, have been untrustworthy, and with no definite guide for testing, that of the U. S. P. being of a very low standard. These objections no longer obtain, however, for manufacturers have been led to provide accurate tests, and now disseminate the same in their literature. Thus we find Parke Davis & Co. issue a work on "Digestive Ferments," that is accurate in all details, and further, they have placed upon the market a new pepsin of higher digestive power than any heretofore introduced, and possessing the exceptional advantages of being absolutely *free* from ptomaines, readily soluble, and of a digestive power hitherto unattained. Moreover, the standard of pepsin has been raised by the better manufacturers, and it is the practitioner's own fault if he is not able now to secure a preparation suited to his needs.—*Exchange.*

Medical News and Miscellany.

An Italian doctor with the suggestive name of Poppi is said to have invented a new hypnotic.

The New Jersey State Medical Society meets, on June 18, at Asbury Park. A large attendance is expected.

At the next meeting of the Board of Charities it is said that the election of successors to E. Bruen and Prof. Osler will again be postponed.

The Norristown Insane Hospital Trustees have decided to employ men to watch attendants for the purpose of preventing cruelty to patients.

The English Steamship Baltimore City was lately detained at the Delaware breakwater, two of the crew being down with fever. The ship was from Cuba.

Dr. George H. Makuen, of the staff of Cooper Hospital, Camden, has been appointed Assistant Demonstrator of Anatomy in the Jefferson Medical College.

Hypnotism.—It is claimed by some that the thirst and desire for intoxicants can be cured by hypnotism, and a hospital has already been opened in Paris for that purpose.

Burning the huge pile of debris against the bridge at Johnstown was early insisted on by the medical men; but when were the ears of poignant grief ever open to the voice of science?

Messrs. Reed & Carnrick have donated a large amount of sodium hypochlorite, the most powerful disinfectant in the market, to the Pennsylvania Board of Health, for use at Johnstown.

Perhaps nothing could impress one more with the unspeakable horror of the Johnstown calamity than seeing, along with carloads of provisions sent for the living, carloads of coffins—the last want of the dead.

A Clearfield County woman died of septicæmia, following a wound of the palm of the hand, made by a sliver of candy. She refused to allow the physician to remove the candy by an operation.

According to a Berlin correspondent, Prof. Förster, Head Physician of the Royal Eye Hospital in Breslau, maintains that short-sightedness in children is not infrequently due to their wearing too tight-fitttng collars.

Why?—It has been found in experiments at Leipsic that skin grafted from a white to a colored person becomes gradually black, and that black skin grafted upon a white person in time turns white.—*Am. Analyst.*

The combination of medical journals has evidently been recognized as a wise movement. The *Medical Press* of Western New York and the Buffalo *Medical and Surgical Journal* have pooled their issues, and will hereafter appear under the latter name. Both have been publications of sterling merit, and it cannot be doubted that the result of the combination will be a better journal than either.

A BIG tarantula that was concealed in a bunch of bananas bit a fruit vender's hand. The hand immediately swelled up dangerously; but, according to a daily paper, unlimited whiskey saved the man's life. Should the amendment pass there will be a good market for tarantulas here.

A STRONG COMBINATION. — The Philadelphia MEDICAL TIMES, the MEDICAL REGISTER, and DIETETIC GAZETTE have combined as one paper, and will appear weekly as THE TIMES AND REGISTER. We wish Dr. W. F. Waugh, the erudite editor, every success.—*Canadian Practitioner.*

POCKET INVENTIONS.—No invention is complete in America unless it can be reduced to pocket size. Cameras and electric lights have already met the requirements, and now we are told that a type-writer is made so small that it can be carried about in the same convenient receptacle.

STATISTICS seem to show that the mortality from diphtheria is on the increase. For the purpose of increasing the popular knowledge of this fatal and insidious disease the New York Board of Health has issued a circular showing how diphtheria originates and spreads, and giving directions for its prevention and treatment. This action is to be commended.

As predicted in our last issue, the meeting of the Pennsylvania State Medical Society was postponed until September 3. Before adjourning the Society appropriated $1000 to aid the Johnstown sufferers, and passed resolutions calling on all country societies to contribute through the Cambria County Society, of which Dr. F. Shill, Johnstown, is Treasurer.

PROF. PREYER, of Berlin, claims to have noticed various movements in embryos, both voluntary and in answer to stimulation, before any ganglia are developed. Birds' eggs chiefly were experimented on. An opening is made in the shell, and this covered by an unbroken piece of another shell. The egg is placed in an incubator, and by means of the little trapdoor the observations are made.

THE MEDICAL REGISTER, of Philadelphia, has united with the MEDICAL TIMES, of the same city, and the DIETETIC GAZETTE, of New York. Prof. John V. Shoemaker retires from editorial work, while Prof. William F. Waugh, one of the most popular medical writers in America, assumes charge of the new combination, which will be known as the TIMES AND REGISTER. "Here's to success."—Kansas City *Med. Index.*

"THE Albany Dress Club closes its labors for the season with the next meeting" is what we noticed in a daily paper.

It seems that this Club was organized a few months since with a membership of six women, and having reform in female dress as its object.

Though assailed by ridicule, sarcasm, and similar weapons, the membership now numbers nearly a hundred. What their ideas are we do not know; but as it would be difficult to reform woman's dress otherwise than to improve it, we trust that the membership will increase.

A WISE PRECAUTION.—Hereafter the Boston Board of Health will cause the public library card in each family where a contagious disease is found to exist to be stamped, so as to indicate the presence of such a disease there. The library will thereafter decline to allow other books to be taken out on this card until the contagion has been stamped out from the home. When books are returned from such a locality they will be disinfected.—*Exchange.*

A LAY contemporary sapiently suggests to its readers that the potency pills or pellets should not be judged by their size, citing the case of a would-be wise man, who, upon reciving from his physician a dozen minute granules, with accurate directions as to taking them, thought he might expedite matters by swallowing all the insignificant things at a gulp, but the little pellets were strong enough to carry him to the other side.

DR. HOBART A. HARE, who was recently appointed editor of the *Medical News*, and Dr. Edward Martin have been awarded the Warner Prize of $500 offered by the Massachusetts General Hospital for the best essay on the treatment of persons apparently dead from failure of respiration. Dr. Hare has also received the Fothergillian Medal of the Medical Society of London, and the Fisk Fund Prize of the Rhode Island Medical Society for 1885 and 1886.—*Press.*

UNDOUBTEDLY the horrible disaster in Johnstown will result in destroying the reason of a number of the afflicted—great catastrophies always do; but we hardly share the fear of some of the daily papers, that the insane will be so numerous that accommodations will be lacking.

Through the judicious use of disinfectants and other sanitary precautions the danger of any epidemic seems to have been avoided.

KNOWN BY THE COLOR OF THEIR CAPS.—At the University of Paris the members of the different faculties are distinguished by the color of the bands at the base of their *berets*. Thus the law students wear one of scarlet, their pharmaceutical *confreres* a green one, science rejoices in vermillion, medicine in crimson, fine art in orange, Protestant theology in blue, and the School of Oriental Languages in gold, while simple yellow marks the students at the Faculty of Letters.

THEY LOOKED THROUGH COLORED GLASSES.—A gentleman being troubled with sore throat visited a eminent genito-urinary specialist, who diagnosed secondary syphilis, and ordered mixed treatment, which afforded no relief. He was then referred to a neurologist, who located the trouble in the brain, and prescribed strichnia and galvanism, which also failed to improve the throat. Then he went to a laryngologist, who decided that the trouble was catarrhal pharyngitis, and used astringents, which the patient said made him worse. Finally he fell into the hands of a well-known general practitioner, who prescribed for an old standing dyspepsia, and the throat was soon entirely well.—Brooklyn *Medical Journal.*

THE death-list at Johnstown has been happily reduced since our last issue. The physicians who are lost are Drs. C. C. Brinkley, J. C. Wilson, H. W. Marbourg, W. C. Beam, L. T. Beam, J. K. Lee, together with members of the families of Drs. Wagner, Yeagley, Sheridan, and Swan.

Dr. W. B. Lowman, who was a man of wealth, is reported to have lost his possessions.

Dr. J. W. Hammer, a subscriber of THE TIMES AND REGISTER, is said to be the only physician in the valley who escaped without loss.

THE consolidation of the Philadelphia MEDICAL TIMES, the MEDICAL REGISTER, and the DIETETIC GAZETTE, is to be commended, on the ground that the country is overflowing with medical magazines, and any such move that tends to reduce the number and improve the quality is in the direction of gain to the medical journal readers. THE TIMES AND REGISTER, which will henceforth be the designation of the consolidated journal, will be issued weekly under the editorial management of Dr. William F. Waugh, an indication for a successful career for the new enterprize, which we sincerely hope may be vouchsafed to it.—Buffalo *Med. and Surg. Journal.*

THE TIMES AND REGISTER.—This is a new journal, in name only, combining the Philadelphia MEDICAL TIMES, the MEDICAL REGISTER, and the DIETETIC GAZETTE. It appears as a weekly under the above title, but a quarterly number, devoted solely to physiological medicine, will also be published. The journals forming the combination are too well and favorably known to need more than a notice of their union. The Philadelphia MEDICAL TIMES has been an invariably excellent and practical journal, and we observe that many of its leading features have been retained in the new weekly. Dr. W. F. Waugh is the editor. He brings his former staff with him, and further additions are promised. — *Occidental Med. Times.*

Thursday, June 27, 9.30 A.M.—Graduation Exercises of the class of '89. Commencement Address, by the Hon. Henry K. Boyer, of Philadelphia. 8 P.M. President's Reception.

MEDICINE AS SHE IS WROTE.—The *Record* of this city, in commenting on the dangerousness of chewing gum, causes one of our "opticians" to say this about the fair chewers: "If they are chronic gum chewers they are heir to all the infirmities that afflict the chronic whisky drinkers. The greatest injury is caused to the eyes. The muscles of the jaw connect with the spine, and from the spine there are fibrous tissues running in all directions, a number of these extending to the eye are called the optic nerves. These nerves are very sensitive, and when overworked become shrunken and enfeebled, and the process of deterioration in the eyesight begins. The vision soon becomes impaired and eyeglasses must be resorted to."

It is not often that our bright contemporary makes such sad work as the above.

WARNING DREAMS.—A writer in the *American Analyst* says that "apoplexy, epilepsy, and similar diseases are often preceded by frightful dreams in which the sleeper feels himself scalped by Indians, thrown over precipices, or torn to pieces by wild beasts," and that such dreams "should be treated as 'warnings' in the truest sense of that word—as sent by nature to foretell impending evils which skill and wisdom may be able to avert."

But who of us has not had nightmare after nightmare, enough to presage all the diseases in Christendom? The writer of this well remembers that while a boy and reading ancient history he fled for many a continuous night before war chariots with scythes in their wheels, and as his reading varied he was indifferently falling into dens of serpents, fighting Indians with great odds against him, pursued by bloody murderers; in fact, spent his nights in a far more exciting and frightful manner than did the fictitious characters of his daily reading.

Clinical Lecture.

GASTRIC CARCINOMA,

WITH REMARKS ON THE TESTS FOR THE ACIDS OF THE GASTRIC JUICE.

(Delivered at the Philadelphia Hospital, May 25, 1889)

BY JAMES TYSON, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania; one of the Physicians to the Philadelphia Hospital.

GENTLEMEN: I desire to show you a couple of cases to-day of extreme clinical and also practical interest, which illustrate different degrees of a condition which is easily recognized in the first patient. He is a man, fifty-eight years of age, by occupation a morocco-finisher. His family history is negative, and we need not dwell upon it. There is one fact in his immediate personal history to which I will call your attention, simply because he deems it important, and shall refer again to its relationship to the disease with which he is affected. In his work as a morocco-dresser he is obliged to handle a considerable quantity of strong acid, the fumes of which he inhales. This, he claims, has done much to bring on his present condition. One year ago he commenced to complain of pain in the epigastrium, dull, boring in character. His appetite began to fail, and at times he vomited, though rarely. In fact, he presented all the symptoms of a chronic gastric catarrh.

On admission, six weeks ago, he was suffering from pain in the epigastric region, increased on taking food, especially solid food. Since his admission he has vomited seldom, but two weeks ago the vomited matter contained some altered blood. His appetite is poor, digestion feeble and bowels constipated, and he is losing flesh, his weight on admission being 192 pounds, while now it is but 108. He presents a peculiar cachectic appearance, which is becoming more marked. Recapitulating, the main points of the history are a chronic indigestion dating back to November of last year, pain on taking food, especially solid food, a progressive emaciation, only occasional vomiting and in the vomited matter a little blood, which may or may not be significant, and a cachexia which is gradually deepening. The inhalation of the irritating vapor from his business, I believe has nothing whatever to do with the disease from which he suffers, although it is not unreasonable for him to suppose so.

What, then, is the cause of the indigestion of which he complains? Is it a simple chemical dyspepsia where there is a failure of the gastric juice to do its work, or is there a lesion present in the stomach to give rise to this series of symptoms? It is plain there is something more than a simple indigestion. Let us examine his abdomen to discover if there is any local manifestation of disease. It must be remembered that serious local disease may exist and at the

same time not be demonstrable by an external examination, and for months a patient may have all the symptoms pointing to an organic trouble with no manifestation locally. As we make an inspection of this man's abdomen nothing of importance is noted; there is no tumor or swelling present. On percussion we discover in the mid sternal line the hepatic dulness extending from one-third to one-half the distance down to the umbilicus, the normal position. Everywhere else there is a tympanitic percussion note. On palpation there is a tenderness discovered above and to the left of the umbilicus. Deep percussion here gives tympany all around and over this spot, but there is just a little impairment so far as the intensity of the tympany is concerned. In palpating over this region I imagine I can feel a decided swelling, circumscribed, from one and a half to two inches in diameter. This tumor is not nearly so distinct as it was the other day when I saw the patient, but still it is recognizable, and I can, more or less, isolate an area of hardness. I have little doubt of the condition here present. I believe this is a case of carcinoma. You may ask, Why is it that this area of hardness which I felt is not so distinguishable to-day as it was when I saw the patient last? Varying degrees of distention of the intestines by gas will obscure very largely the size of a growth in the stomach, especially if it be of but a small size. This is probably the cause of the difference between the condition to-day and that of the other day.

As to the situation of this cancer of the stomach, I believe it is not the usual one from the symptoms which he presents. You notice that he scarcely ever vomits, and there is nothing of the regular daily or alternate daily vomiting which is so characteristic of cancer of the pylorus. In the vast majority of cases cancer of the pylorus produce obstruction, and to this succeeds dilatation of the stomach, with frequent vomiting of its contents. As the disease progresses and the stomach becomes tolerant, a considerable accumulation will take place, and the patient will then vomit at longer intervals, as once in three or four days, and then throw up a large quantity, gallons even.

Hemorrhage has been alluded to as a symptom in this case. In certain forms of cancer there is the occurrence of large hemorrhages, and this symptom often makes the question of diagnosis between cancer of the stomach and gastric ulcer a nice one. The hemorrhage is too slight in this case to be of significance from any standpoint.

The question of the diagnosis of cancer, as distinguished from indigestion from functional causes, has received a great deal of attention of late, and caused considerable investigation to be made as to the chemical constitution of the contents of the stomach. In no disease is the production of an efficient gastric juice so much interfered with as in cancer, because of the destruction of the gastric follicles, and it is especially the hydrochloric acid which is deficient. Two methods are used to test the efficiency of the gastric juice. In the first, or physiological, some of the juice is removed from the stomach by means of the sound and digestion practised with it on boiled egg albumen. For this purpose the patient's stomach should be washed out the previous evening, if possible, and in the morning a meal of egg with bread and butter, together with hot milk, water and sugar, administered. In an hour a soft, flexible tube, eighteen or twenty inches long, lubricated with milk, is introduced into the stomach. Light pressure on the abdomen facilitates the removal of the gastric fluid. Any admixture of food may be filtered out, and the experiment proceeded with at a temperature of 95° to 100° F. Or a method suggested by Korczynski and Jaworski may be pursued. They introduced by the sound two hundred cubic centimeters of ice-cold water on an empty stomach, withdrew the sound, and in ten minutes reintroduced the sound and aspirated the gastric contents, which include gastric juice diluted with water—the secretion of the digestive fluid being stimulated by the ice-cold water. Another method of determining the efficiency of the gastric juice, physiologically, is that of Riegel, who gives the patient a meal of mixed food, and after six or seven hours removes the undiluted gastric contents with the sound. Digestion should be complete in seven hours, and therefore, if after this period any portion of undigested food remain, it is evident that digestion has been abnormally delayed.

These methods, however, involve much time and trouble. It is easier to test for the acids of the gastric juice. The acids found in the gastric juice are hydrochloric and lactic. The former is generally regarded as indispensable to digestion. The significance of the lactic is not so certainly determined. Thus, Ewald[1] believes that it plays a most important part during the first hours of digestion, and that through its operation peptone appears in the aspirated contents, fifteen minutes after the ingestion of food. R. Schaeffer,[2] however, claims that the peptone is always present in the watery extract of the foods used by Ewald. Cohn and v. Merring[3] consider that both lactic and hydrochloric acids are present with a mixed diet, while with an animal diet hydrochloric acid alone is found, but Ewald claims that lactic acid develops even after a purely animal diet. Lactic acid is further developed in the stomach as the result of fermentation, when it may contribute to conditions of hyperacidity. I am myself inclined to believe that lactic acid is but a secondary factor in gastric digestion if it plays any useful rôle whatever, and certainly recent observations go to show that hydrochloric acid is far more important. Accordingly, most of the tests I shall give you are for the inorganic acid.

Günzburg's test is regarded as one of the most reliable. It is made by dissolving phloro-glucin, two grammes, vanillin, one gramme, in thirty cubic centimeters of alcohol. One or two drops of this are mixed with an equal portion of the gastric fluid, and heated gently in a shallow porcelain capsule. As the fluid is moved back and forth, a purple or red color is produced at the edges of the fluid if the acid

[1] *Virchow's Archiv.*, Bd. 101, S. 351.
[2] *Zeitschrift für Klin. Med.*, Bd. 15, p. 174, 1888.
[3] *Deut. Arch. f. Klin. Med.*, Bd. 39, N. 3 and 4.

be present. Schaeffer claims that no other constituent of the gastric juice produces this reaction, and especially do not the organic acids even in concentrated solution. Hence, he regards it as the most infallible test for free hydrochloric acid. In watery solution hydrochloric acid may be detected in the proportion of $\frac{1}{2}\frac{1}{0}$ of a part per 1000.

On the other hand, *Uffelman's test*, the *carbolated iron test*, is a good test for the organic acid, lactic acid. It consists of a 4 per cent. solution of carbolic acid to which as much tincture of the chloride of iron is added as will produce an amethyst color. Lactic acid added to this produces a yellow color, while hydrochloric acid altogether decolorizes it. Other mineral acids also decolorize it, and therefore it is not a reliable test for HCl. We will now try some of our fluid for this reaction. It is best to use a dilute solution of the sesqui-chloride, and the test fluid should be freshly made. I add enough of the iron solution to bring about this coloration; one or two drops are sufficient. Now, the addition of the gastric juice or lactic-acid containing fluid should produce the yellow color. By this test it is said $\frac{1}{100}$ part of lactic acid in 1000 may be recognized, but sugar solutions must be eliminated, as they act similarly.

The *aniline* colors also furnish tests for the hydrochloric acid of the gastric juice, and among the best known of these is the *methyl violet*, but it is of disputed value. For not only does hydrochloric acid decolorize it, but also a 5 per cent. solution of lactic acid, a strength often present in gastric fluids, while peptone also reacts similarly. The test is thus applied: A drop of a weak, watery solution is placed on a porcelain capsule and one or two drops of the suspected solution added. If hydrochloric acid is present, the violet is turned into blue. One-tenth of a part of HCl in 1000 may be thus recognized.

Another of the aniline color tests is *Congo-red*, which is best used in the shape of a stained paper, the red of which is turned blue by the action of hydrochloric acid. This also is an unreliable test, because a solution of lactic acid has the same effect if double the strength as that of hydrochloric.

Another test is the *Tropäolin test*, for hydrochloric acid also, most satisfactory when used in the form of the Tropäolin paper, as suggested by Boas,[1] who uses an alcoholic solution of tropäolin, enough to saturate blotting-paper. If pieces of the dry paper are touched with dilute HCl, and heated in a porcelain capsule, there appears at the edges of the spots a bright-lilac color which promptly disappears. No organic acids produce this action, while solution of free HCl in the proportion of ½ of a part to 1000 reacts distinctly. In the gastric juice, however, the reaction is less distinct. Using to-day an aqueous solution in a test-tube, and adding some of the filtered gastric contents from our patient, no reaction is observed. We may, therefore, conclude that no hydrochloric acid is present. This test is regarded by Schaeffer as less delicate than Günzburg's test, but better than the rest.

Mohr's test for hydrochloric acid, which consists in a concentrated solution of the acetate of iron, one part; a concentrated solution of rhodanated potash, four parts; distilled water, twenty parts, is especially praised by Ritter and Horsch[1] for reliability and sharpness. The fluid is a ruby-red one, and one-half a part of HCl in 1000 of distilled water will produce a mahogany-brown coloration. In actual practice with gastric fluids Schaeffer has often failed with Mohr's test and tropäolin, where Günzburg's and the methyl violet succeeded.

Now, in the case of our own patient, more than one of these tests applied to the gastric contents withdrawn after food ingestion shows the reaction for hydrochloric acid to be feeble or wanting, so that this fact may be added in addition to the others named in confirmation of the diagnosis.

I may mention, however, in passing, that there are other forms of gastric derangement in which hydrochloric acid is deficient. In chronic gastric catarrh where due to passive hyperæmia, whether due to hepatic or cardiac disease or the use of alcohol, there is such a diminution. The acids of the gastric juice are also increased at times. This is especially the case with gastric ulcer, in which not only is hydrochloric acid increased, but organic acids, especially lactic and butyric, are added during faulty digestion as the result of fermentation. It is to be remembered, too, that hydrochloric acid may exist in combination with bases, and thus elude detection.

At the present day we are greatly aided in the treatment of cases of this kind by the use of partially or completely digested foods, of which so many are now to be had. If the stomach is in the condition of this man's, where there is sufficient patulousness of the pyloric orifice to carry the food onward, we may give peptonized milk, or any one of the meat peptones. Solid food of any kind must not be given. Peptonized milk recommends itself by its cheapness and ease of preparation. If the tumor is of the pylorus, not only is digestion weak, but absorption is almost impossible (because most of the absorption takes place from the small intestine), and we must make use of the rectum. For weeks, and even months, we may thus be enabled to nourish our patients by the use of peptonized food. They usually have an irresistible inclination to taste the articles of food, and this is the greatest obstacle to overcome. Of course, the ultimate result is necessarily fatal.

Our next case illustrates the same condition, but in a more advanced stage. The patient is a Hungarian woman, who cannot speak a word of English, and so the history of the case can only be derived from a physical examination. Her appearance, however, at this stage renders the diagnosis easy.

She was admitted on February 11, last, with no history. She had very much of the appearance presented by the man you have just seen, since the disease was then not so far advanced as at present, but she presents now some different conditions. She is a vomiting case. Invariably after some accumulation in the stomach she vomits, and so we conclude at once that there is an obstruction at the pylorus.

[1] Ueber Tropäolin papier als Reagens auf freie HCl in magensaft, *Deut. Med. Wochenschr.*, 1887, No. 39.

[1] *Zeitschr. für Klin. Med.*, Bd. 13, H. 5.

It requires no great skill to recognize a tumor here. Not only do we discover the tumor by palpation, but it is easily seen as a nodular, uneven mass above and to the left of the umbilicus. But, as I have said, it is by no means invariable to have so easily recognizable a tumor even at an advanced stage of carcinoma ventriculi. The cachexia and wasting will often be present a long time before we can find the tumor, and this fact, years ago, was regarded as favoring the view of a primary cachexia. At the present day pathologists, for the most part, consider cancer as primarily purely local, and that the dyscrasic state or cachexia is a secondary one. To such a local growth we admit, of course, that there may be a hereditary tendency.

As to treatment in this case, the woman, as I have said, is a vomiter. It would, therefore, be futile to expect to nourish her successfully by the mouth, and she has been under the use of enemata for a considerable length of time. That they are, however, insufficient is shown by her progressive emaciation. An examination of the vomited matter for hydrochloric acid has also been made, and failed to discover the presence of the acid, and although we must not forget that the test may be negative, and still hydrochloric acid be present in combination with bases, nevertheless, if hydrochloric acid to be of any use in digestion is present, it will react.

Another point of diagnostic interest here is found in connection with the situation of the tumor. It is a singular fact that no difference where the tumor is located in the gastric walls, the external manifestation of it is generally to the left and above the umbilicus. In cancer of the pylorus one would expect it to be the right, but it is never found there on external examination. In the case of the man it does not follow that he has not cancer of the pylorus because of the absence of vomiting. More frequently, when there is not vomiting, it is in the vicinity but not at the pylorus. Cancer may occur at the cardiac end or in the middle belt. If at the cardiac end there is often obstruction to deglutition. This is not present in the case of the man, so the cancer must be located somewhere between these points, but still, probably, near the pylorus. When in the middle belt, cancer often rides the curvature as a saddle does the back of a horse. A soft cancer is the most common variety at this point, and it is attended with copious hemorrhages; but as hemorrhage is not present in either case, the point of development in the case of the man must remain in doubt for the present.

The presence of indican in the urine is another clinical fact to be mentioned in this connection. It is said that indican is increased in the urine when there is cancer of any of the abdominal organs attended by obstruction, and especially of the stomach and intestines. This is by no means distinctive, but it has a certain value, and the test should be made. We have tested the urine of the man, and the indican has been found slightly increased in quantity. In the case of the woman, we have not made the examination. The test consists in taking a drachm of pure hydrochloric acid and dropping in while stirring ten to twenty drops of urine, and if the indican is increased in amount, we have a beautiful violet or blue color produced, while if it is normal in quantity, a pale yellowish-red color only is developed.

Original Articles.

ELECTRICITY IN GYNECOLOGY.

By W. H. WALLING, M.D.

ON October 29, 1888, Mrs. C., aged thirty-eight years, English, married and the mother of four children, the youngest being ten years old, came to the writer's office for treatment. She had been suffering since the birth of her last child with a great and growing discomfort in the pelvic region, with steady enlargement upwards, until at this date she measures forty-seven inches around the abdomen just below the umbilicus. She states that two years since she was operated upon for laceration of the cervix with but partial success; a severe pelvic and general peritonitis resulting. She was in one of our hospitals for treatment recently, some five months, and discharged as incurable.

The abdomen was so excessively tender that little could be determined by external manipulation. By digital examination the uterus was found greatly enlarged from fibroid degeneration, well down in the pelvis, tender to the touch, the canal measuring three and one-half inches plus, and quite large. Frequent and severe hemorrhages occurred. The kidneys were very sensitive, their secretion being at times overabundant, at other times very scanty. The patient was extremely nervous and very susceptible to the electric current. At first, central faradization and galvanization of the abdomen was all that was attempted by way of treatment. As the sponge electrode was passed over the kidneys the patient said that she could distinctly feel the urine pass from them and down the ureters into the bladder. It was noticed that a free evacuation of the bladder followed the application of either the Faradic or galvanic current, when the urine had been scanty, affording great relief.

These external applications were continued up to January 7, 1889, with marked improvement of the general health. On this date negative cauterization of the uterus was made, giving, however, but twenty milliampères for three minutes, the positive pad being on the abdomen. This caused some discomfort. On the 10th, the same treatment was given, increased to twenty-five milliampères. This caused considerable pain of a bearing down nature, followed by a profuse hemorrhage the next day, lasting, however, but a short time compared with previous attacks, and readily controlled without the use of ergot. On the 16th, general treatment was given as at first, and on the 19th, positive cauterization of the uterus was commenced and continued at the office, twice each week, as circumstances permitted, alternated from time to time, with general treatment. Her monthly periods were passed with less and less discomfort, being less in quantity and showing more serum than blood, the abdomen steadily decreased in size, the

uterus becoming more movable and less painful. At no time was over thirty milliampères used, generally but twenty-five, for five minutes, up to April 22, when fifty milliampères were given, but quickly reduced to thirty as this quantity caused too much pain.

The abdomen now measures about forty inches, its normal size, and the patient says she feels the same relief from pressure as after a confinement. The uterus is in its normal position, and she is at least symptomatically well.

Several severe attacks of polyuria and cystitis interfered with the treatment and were not accounted for until it was found that the patient was addicted to gin drinking, periodically, a habit of years. She was so sly with her potations, and was so much of a lady, that it was not suspected, and the cause of the attacks was sought for in every direction but the right one.

At present there are still some adhesions, the result of the cellulitis, and treatment will be continued suitable for their absorption.

At times she suffers very much with pruritus vulvæ, for which the negative pole is applied by a large bulb electrode covered with absorbent cotton, giving from two to five milliampères for one or two minutes at a sitting, with prompt relief.

Particular attention is called to the low power used and good results obtained. Stronger currents would have been used but they caused too much pain, which is to be avoided if possible.

Now, while Apostoli and some others claim that they administer high current strengths without causing pain, I have yet to see the patient that did not complain of experiencing more or less pain even with mild currents; and without a reliable milliampèremeter one can tell very little about current strength. Indeed at times without such an instrument one would have supposed from complaints made that a very strong current had inadvertantly been turned on. I cannot coincide with those who claim that no pain is caused by such applications, agreeing rather with Dr. Martin, of Chicago, that if properly used they do not cause sufficient pain to require an anæsthetic.

Pain is an element we ought not to ignore or treat lightly, and yet too much stress must not be laid upon it, as often fear or excitement is the prime factor in the application. That there is a great difference in the susceptibility of patients is well known. This one and several others appeared to suffer as much or more with twenty-five or thirty milliampères, as some others with one hundred and fifty to two hundred milliampères, under the same apparent conditions.

Great gentleness and care in the introduction of the uterine electrode is necessary, and if the positive pole is used it must be made of either platinum or gold. It would seem unnecessary to reiterate this statement, but frequent inquiries upon this very point is the reason. Massey's electrode is the one best adapted to this kind of work, not only by its simplicity, but it is so readily sterilized, being insulated with shellac instead of rubber.

Dr. A. Lapthorn Smith has called attention to a very important point regarding the position of the indifferent electrode in the treatment of uterine fibroids. He thinks that the clay or cotton pad should not be kept upon the abdomen, but after a number of treatments should be changed to the back. Some of our electricians will say this is unnecessary, as experiments with the galvanic current and a barrel of salt water showed that the current does not pass directly by the shortest route between the electrodes, but that some lines start out in opposite directions, thus acting upon substance not supposed to be included in the circuit. This takes place in a homogeneous liquid like salt water, but can it do so to the same extent in the human body? Experiments with chemicals and results obtained are not always sufficient guides for treatment of diseased conditions.

A good deal has been said about divers washings and vaginal douches both before and after intra-uterine treatment. Now while this is necessary where puncture is made, I fail to see that it is in ordinary treatment. The current itself is antiseptic, and there is far more danger from unclean instruments or hands than from any other source. But we are told that it is the destruction of tissue by the current and its subsequent decomposition which produces the sepsis, etc. Experience, however, disproves such statements as a rule. I believe that the septic cases were caused in many instances by dirty hands or instruments as above stated.

A few words as to the after-treatment of patients. If the application is made at the homes of the patients, they are directed to lie down for an hour or more, and if high currents have been used to remain in bed until the following day, or even longer if necessary. Office patients are given a lounge upon which to rest awhile before going out, and directed to lie down upon reaching home. But how about out-patients at the hospitals? They cannot be given couches for rest, there being neither room nor time, and so they go immediately on their way after leaving the operating table. Thus far, however, I have noticed little if any bad effects following intra-uterine or other applications of electricity in this class of cases when they followed the instructions given, which were to lie down upon reaching home and keep very quiet the following day. They are told to expect more or less pain on the day following the application, so are prepared for some discomfort.

Much stress is laid by many operators upon using clay for the abdominal pad. It is undoubtedly safer and better for all very strong currents, or say for all above one hundred milliampères, but for all below this, absorbent cotton is preferable, both on account of cleanliness and convenience.

Both cotton and clay should be always well-wetted in quite warm water before applying. I have seen operators apply a clay pad wetted with cold water and wondered that they did not have more trouble with their patients than seemed to follow. It is quite possible, even probable, that such cold clay poultices have been the cause of any bad after-effects, rather than the current itself, even if it was a little overdone.

ERYSIPELAS OF THE LARYNX.

By MAX THORNER, M.D.,
CINCINNATI, OHIO.

THE larynx may be affected with erysipelas as well as the pharynx. Generally, the affection is secondary, spreading by contiguity from any region of the head along the mucous tracts of the nose, mouth, or ear, the first being apparently a common seat of the primary affection. There is, however, sufficient clinical evidence that an erysipelas of the pharynx and larynx may follow an attack in a distant part of the body.

Primary erysipelas of the larynx had been described in the prelaryngoscopic time; and we find a number of modern authors admitting the possibility of primary erysipelas of the larynx, or reporting cases thus diagnosticated. Above all, Prof. Ferdinand Massei (S. C.), of Naples, who has shown, in a number of publications, that primary erysipelas of the larynx is a disease *sui generis*, and that many cases of so-called phlegmonous laryngitis are, in reality, nothing but an erysipelatous inflammation of the mucous membrane of the larynx. The following remarks are more especially based on the observations of the author just named:

The etiology and pathology of this affection are the same as in other parts of the body. The disease is an infectious one, and caused by the presence of some pathogenic microörganisms—the streptococci discovered by Fehleisen. This fact renders all former theories obsolete, as to the existence of a traumatic and an idiopathic erysipelas, the latter being mainly the result of a "cold." Massei is of the opinion that lesions of the epithelium covering the base of the tongue, the epiglottis, the aryepiglottic folds, and the interarytenoid fold, favor the entrance of the streptococci, these regions being constantly exposed to numberless irritations. The abundance of lymphatic tissue in these parts readily accounts for the course that the affection takes.

The *symptoms* are the following: There is in the outset hoarseness, which sometimes rapidly increases to complete aphonia. Swallowing is difficult and painful. The temperature rises to above 104° F. often remitting to 100° F. Yet the fever is of an irregular type, depending upon the progress of the laryngeal affection. An initial chill may or may not be observed. The lymphatic glands around the larynx and trachea are frequently enlarged, and the whole region is always painful to the touch. The general symptoms which we find in erysipelas are never entirely missing. Upon examination with the laryngoscope we may find, in many cases, only the signs of an acute catarrhal laryngitis: intense hyperæmia, hypersecretion, and slight swelling of the mucous membrane. In other cases there is a more or less developed œdematous swelling of the epiglottis, the aryepiglottic folds, or the interarytenoid membrane. This œdema is wandering—a pathognomonic sign of erysipelas according to Massei. Sometimes blisters, filled with serum or pus, are found; they burst, and leave small crusts adhering to the mucosa. With the increasing swelling the dysphagia and dyspnœa increase, until the latter is the most prominent symptom, threatening death from suffocation.

The *diagnosis* is mostly to be made without difficulty. The rapid swelling of the mucosa, the wandering nature of the tumefaction (in case a laryngoscopic examination is practicable), and the height and type of the fever are very significant. The latter is of great importance for the differential diagnosis, since neither the acute catarrhal laryngitis nor the acute œdema of the larynx is associated with a similar rise of temperature. Furthermore, the history of the case is of importance. A simple œdema of the larynx may be caused by injuries, as, for instance, by scalding the throat, by continuation of a tonsillitis or pharyngitis to the larynx; also, by albuminuria, from whatever cause; by circulatory disturbances, by syphilitic, tubercular, or cancerous disease of the throat. In erysipelas we can exclude these factors. If an erysipelas in any other part of the body has preceded the laryngeal affection, or if the latter is followed by a facial erysipelas, or by subsequent affection of the lungs, the diagnosis of erysipelatous affection of the larynx cannot be doubted.

The *course* of the disease is usually a very rapid one. The local manifestations may remain confined to the larynx, or may extend to the pharynx, and from there to the face, or downward to the trachea and bronchial tubes. Three different issues are possible: First, recovery in consequence of a gradual resolution; secondly, death from suffocation, unless operative measures are resorted to; thirdly, death from collapse, or from congestion and œdema of the lungs.

The *prognosis* is always doubtful, As a rule, it is better in those cases where the local symptoms are only those of an acute laryngitis, although œdema may set in at any moment, and increase with such rapidity that death may ensue within a few hours. The prognosis in primary erysipelas of the larynx has also been regarded as more favorable than that of secondary. There is, however, one form of the disease in which the local symptoms of the disease are less marked, but the general symptoms, as tendency to collapse and complications on the part of the lungs, are more prominent. This adynamic form, only found in old people, proves always fatal.

The *treatment* is, regarding the general symptoms, the same as for erysipelas in general, consisting chiefly in the liberal use of stimulants, and the exhibition of antipyretics, whenever the temperature is very high, without showing any tendency to spontaneous remissions. The treatment of the local symptoms may be briefly summarized as follows: In the beginning ice applications around the neck and the swallowing of cracked ice are sometimes of service; the same may be said of alkaline sprays. The local applications of morphine (care being taken not to narcotize the patient), or still better, as I would suggest, of cocaine, are often indispensable to relieve the pain. By using the latter we need not be in fear of the constitutional action of morphine, which sometimes has, by putting the patient fast asleep, resulted in death from suffocation. Dr. Daly, of Pittsburgh, and

others have recommended to apply to the neck large mustard plasters, which would, by their revulsive action, tend to change the internal erysipelas into a superficial one. When the dysphagia increases to such an extent that the patient cannot swallow any longer, feeding with the aid of the œsophageal tube, or by rectal injection, must be practised. As soon as the dyspnœa becomes threatening, hypodermatic injections of pilocarpin, from gr. 1/6 to gr. 1/3, may be tried. If these prove ineffective, scarifications of the œdematous tissues must be made; and if these fail, tracheotomy must be resorted to. This operation seems to be preferable to intubation in conditions of this kind, since the upper opening of the tube is very likely to be buried between the swollen tissues.

CONGENITAL ABSENCE OF A PORTION OF THE ANTERIOR ABDOMINAL WALL.

(Reported at the meeting of the Philadelphia Academy of Surgery, June 3, 1889.)

By J. M. BARTON, M.D.,
Surgeon to the Jefferson College Hospital.

MRS. C., of this city, was delivered, by Dr. John Graham, on November 3, 1888, at 3 A.M., of a female child. At the request of Dr. Graham, I saw the child at 1 P.M. of the same day, and found a healthy looking female child, fully developed, except the sagittal suture was still open to the extent of half an inch.

There was a tumor at the umbilicus nearly the size of an adult fist; it was composed of omentum and intestines, which had protruded through an opening over two inches in diameter in the abdominal wall. The tumor was two and a half inches in height, and about three inches in diameter, and was slightly pedunculated. It was covered by a thin layer of the expanded gelatinous matter of the umbilical cord, which was as transparent as glass; the intestines and omentum could be distinctly seen through it, and after they had been returned to the abdominal cavity the left lobe of the liver could also be recognized.

The cord had been tied, and joined the tumor about half an inch to the left of its apex. The vessels of the cord could be traced running down the left side of the tumor and entering the abdomen at the extreme left of the opening, and midway between its upper and lower extremities. The child appeared to be otherwise in perfect health, and had already made vigorous efforts to obtain nourishment. It seemed to be free from pain, except while the intestines were being reduced, which was done with some difficulty, as the abdominal cavity seemed scarcely large enough to contain them. A pad of cotton was then placed over the umbilicus, and a firm flannel bandage bound around the child.

I met Dr. Graham for the purpose of operating at 12 o'clock on the following day, when the child was thirty-three hours old, permission to operate not having been obtained before.

On removing the dressings, which had retained most of the intestines in the abdominal cavity, the hernia was immediately reproduced, but owing to the shrinking of the gelatinous tissue which formed its sac, it was not as large as the day before; it now measured six and three-quarter inches in circumference and four and a quarter inches over its convexity.

The covering was now quite opaque, though the abdominal contents could still be indistinctly distinguished through it. It readily broke down under the fingers, and was quite offensive, requiring repeated applications of a solution of bichloride of mercury for the comfort of the operators. The intention had been, if the parts were found in the same condition as the day before, to pass long hare-lip pins across the opening, bringing its edges together and leaving the sac on the outside to shrivel and dry. As this proved on trial to be ineffectual, the entire sac was trimmed away. About half an ounce of opaque serum, with flakes of lymph floating in it, ran from the abdominal cavity, and the bowels exposed were now highly inflamed, being of a deep red color, with patches of lymph lying upon them and gluing them together. Thinking the peritonitis was probably purely local, and that the rest of the abdominal cavity was protected from infection by these adhesions, we were careful not to rupture them. The bowels were kept in place by an antiseptic sponge, while the edges of the opening, which measured six and a quarter inches in circumference, were freshened and brought together with seven hare-lip pins. A space of an inch was left between two of the pins for drainage. The umbilical vessels passed through this opening and acted as drainage threads. The closed wound was dusted with iodoform and dressed with mercurial gauze.

As there was great tension on the pins holding the parts together, and it seemed probable that they would ulcerate through in a few hours, two pieces of Mead's adhesive plaster, each about six inches square, were placed one on each side of the wound, with the extremities that ran toward the spine cut into many tails. They approached in front to within an inch and a half of each other, and were laced together by a strong cord placed over the dressings.

November 5.—Child doing well; no fever; cries but little; the wound looks well and is not offensive.

November 6.—Slight discharge of pus through opening.

November 7.—About two drachms of pus.

November 8.—Six of the pins removed; wound slightly offensive; about three drachms of pus discharged.

But little pus was discharged after this date. The wound was kept firmly supported by the plaster for two weeks and dressed daily. As it was then firmly healed it needed no further attention. The resulting scar is three and a half inches long, and the child appears to be in perfect health. This condition, in a slight degree, is not very rare, but I am not aware of

any case where the hernial protrusion was so extensive, except one reported as a laparotomy in a child sixty hours old, by Dr. W. Stolypinski, in the *Centralblatt für Gynæcologie* of March, 1889. The operation was performed at the clinic of Prof. Phænomenoff, of Kasan, Russia. The tumor in his case was the size of a goose egg, but the hernial opening was quite small, making it difficult to reduce the intestines; but there appeared to be no difficulty in retaining them after they were reduced. The opening was closed with silk and catgut. This child also made a good recovery.

I would scarcely call this operation a laparotomy, yet the dangers from shock and intestinal exposure are about as great.

FOUR NARROW ESCAPES FROM DEATH FROM HYPERANÆSTHESIA,

AT SURGICAL OPERATIONS.

By LLEWELLYN ELIOT, M.D.,
WASHINGTON, D. C.

BUT few operators doubt the danger attending the administration of the anæsthetics, ether and chloroform, and still fewer are ever brought face to face with instances of the practical illustration of these dangers. It is not my purpose, at this time, to search the literature of hyperanæsthesia from ether and chloroform, but merely to recite four cases in which I had narrow escapes from death.

In the administration of anæsthetics, my preference is for chloroform, first, last, and all the time; this preference is based upon the conviction that it is the best and the safest, and even the mildest may prove a source of disaster. I do not trust to inexperienced hands to superintend the process of its administration. Every precaution is taken to avoid giving too much, and no crowding, except in extreme cases, is permitted. Sufficient air is allowed to enter the lungs along with the anæsthetic to accustom the patient to the presence of the agent, thereby not putting him in constant fear of suffocation. The pulse, the respiration, and the face are watched for the first signal of danger. Everything about the neck, chest, and abdomen is loosened; unnecessary talking and bustle are not encouraged.

I have profited by the lessons I learned in the four instances which have fallen to my lot. They will be stated briefly.

CASE I.—Mary C., white, aged thirty years, attempted suicide October 21, 1879, by inhaling chloroform. When seen the narcosis was complete. Under the inhalations of the nitrite of amyl, she revived and was discharged from treatment the next day.

CASE II.—Johnson B., colored, aged seventeen years, was anæsthetized May 8, 1881, for amputation of the fingers. Without warning he became pulseless and ceased to breathe. Resort was had to spanking, shaking, and cold water to the face. In the shaking, he slipped from the table head foremost, and being a heavy fellow, he could not be picked up immediately. His falling and hanging head down revived him, before the nitrite of amyl bottle could be opened.

CASE III.—Lottie A., colored, aged three days. Owing to the fragility of the umbilical cord and an hereditary tendency as a bleeder, there was frequent hemorrhage from the stump. On March 20, 1889, I met the attending physician in consultation. Pressure and a new ligature afforded but temporary relief, so I introduced hare-lip pins and twisted around them a strong thread. For some hours this proved successful. At 12 o'clock, on March 21, we administered the alcohol, chloroform and ether mixture, and I proceeded to open the abdomen so as to pass a ligature around the cord before its exit, and then fix it in the wound. Little progress had been made in our operation when the child ceased to breathe, and no pulse could be detected at the wrist. The child was immediately suspended by the feet, and in a few minutes it had revived sufficiently to allow us to proceed with our operation. It succumbed a second time and was revived by the same means. The operation was finished, but the child died on the next day.

CASE IV.—Daniel D., colored, aged seventeen, was first seen on April 10, 1889. Diagnosis: Syphilis, gonorrhœa, and phimosis. During the gonorrhœa, he was to be circumcised on April 19. Present: Drs. R. S. Hill and R. A. Pyles. The anæsthesia was commenced with ether, and continued with an admixture of ether and chloroform. There was no crowding or hurry. The ether appeared to have a very depressing effect on him, but this passed off when chloroform was substituted. As I was about to operate the breathing ceased and the pulse stopped. He was drawn to the edge of the bed, with his head hanging down. This had no visible effect. He was then held up by the feet. For some minutes water ran from his mouth and nose, the eyes were set and staring, the face puffed; no pulse could be detected; no respiration was perceptible; no evidence of life was apparent. We were beginning to despair when a faint, scarcely perceptible respiratory effort was noticed. Dr. Pyles gave hypodermatics of whisky and of whisky and aqua ammonia. A few faint efforts at respiration reassured us, and when the nitrite of amyl bottle arrived, although ten minutes had elapsed while he was suspended, the suspension was continued about five minutes more, in addition to the inhalation of the amyl. The amyl was used unsparingly, and at the end of half an hour he was conscious and out of danger.

Such has been my experience with cases of hyperanæsthesia at surgical operations, and I trust my success in their treatment will prove useful to others; but I shall always regret the publication of this paper, should it be the cause of recklessness in the use of these potent agents.

This method of resuscitation — the suspension method—has been called the "Nélaton method," but I fancy it is of a much older date, as Dewees,[1] in 1828, mentions the suspension method as follows: "By placing the child's mouth downward, and holding the body and hips higher than the head; at the same time gently shaking the child, so as to disengage any mucus that may be lodged in the trachea. By pro-

[1] Dewees, "System of Midwifery," p. 188.

ceeding in this manner, I have often had the satisfaction of seeing the child restored under very discouraging circumstances."

Nélaton employed this method in 1857. The value of this method in childbirth, I have discussed elsewhere.[1]

Chisholm[2] read before the Baltimore Academy of Medicine a paper entitled, A very valuable lesson for those who use Anæsthetics, in which he vigorously advocated this method of resuscitation. It is the most notable contribution to the subject under discussion of which I have knowledge.

HUNTING THE GERM OF YELLOW FEVER.

By FRANK S. BILLINGS, M.D.,

(Director of the Patho-Biological Laboratory of the State University of Nebraska.)

[Concluded from page 152.]

HERE we have, however, one and the same organism, not only found in "a series of cases," but also the only one found by other observers with any degree of constancy, and Lacerdo has also told us that he also found it "without exception" in six cases.

This is positive evidence, and every competent investigator knows the value to be placed upon negative evidence in such cases.

I am perfectly well aware of the rules promulgated by Robert Koch as necessary to be fulfilled before the complete chain of scientific evidence can be said to be perfect. They are as follows:

1. One organism must be found in an absolutely pure condition in the tissues of an individual that has perished from a given disease.

2. That microörganism must be isolated from those tissues and cultivated in an artificial manner independent of them.

3. The same disease must be produced in healthy individuals of that species of animal life in which such a disease occurs under conditions of natural infection by the intentional introduction of such organisms, either in a natural way or artificially.

Naturally, the last postulate is very difficult to carry out in relation to diseases limited in their natural occurrence to the human family.

Undoubtedly, the above rules are correct, but when we cannot follow them out, as in many human diseases, what then? Are we to neglect the teachings of common sense? Has Koch fulfilled them in Asiatic cholera? And yet, no competent person doubts the etiological importance of the celebrated "komma" in that disease.

Those are the rules of the extreme bacteriological school, but not one competent pathologist would be guilty of carrying them out to such a severe conclusion as Sternberg, when he says:

"Evidently, if any one of these microörganisms was found in a considerable series of cases the fact would be decidedly significant, and would afford presumptive evidence that the parasitic organism found bore some relation to the morbid process."

"*But even if one and the same microörganism was found in every case, the final proof of its etiological import would depend upon its isolation in pure cultures and the production of the characteristic phenomena of the disease in one of the lower animals, or, in the absence of a susceptible animal, in man himself.*"

Whew! That is what I call "straining at a gnat and swallowing a whole camel." Such language as that can only emanate from one most seriously wanting in clinical and necroscopical experience, but, above all, in pathological acumen and rational common sense. I am perfectly well aware that the whole ultra-bacteriological school will raise a hurricane of indignation about my ears, but, nevertheless, I do say that such language as that is absolutely insane under certain circumstances. It is on a par with some who teach that a physician cannot diagnose tuberculosis except by the microscopic demonstration of the tubercle bacillus. What would Lænnec say to such a remark as that? What would Virchow say to a student out of his school who should preach any such absurd doctrine?

We, who are busy day in and year out, in the examination of small vials, or specimens, brought by farmers from all over such States as Nebraska, know a thousand times better than to insist on the necessity of any such nonsense being carried to that extreme. Were that true, every time a farmer brings me blood, and I find bacillus anthracis in it, I should have to wait and inoculate and cultivate before I could give him an answer or advise him what to do. Were that really so, then all our clinical and pathological knowledge were of little avail.

Were that so, then the sacred few who have taken holy communion at the bacteriological table of Robert Koch are the only masters and leaders, and all others who have gone before, and all of us unsanctified ones who have not tasted of that special fruit of the tree of knowledge, ignoramuses and unfit to be trusted.

But let us come to the point.

What is the yellow fever as a pathological entity? Leaving out of consideration Drs. Sternberg and Gibier (who seem to have got lost somewhere in the intestines "hunting the germ of yellow fever," and who appear to be blind in the hunt), all pathologically competent observers, past and present, *agree that the yellow fever is a septicæmia.*

Being, then, a blood poison, the germ must be in the blood. *It is in the blood as my sections show.* Not only that, but we have mountains of exact testimony showing that other microörganisms of this group do produce septicæmiæ and a specific septicæmia in certain well-known species of animals. For instance, the Southern cattle plague, the swine plague, the hen cholera, the German wild seuche, and my new corn-stalk disease, are all septicæmiæ, and all caused by ovoid-belted germs. But each of these diseases has something peculiar about it which makes it different from the others. The wild seuche attacks deer, cattle, and swine; the swine-plague, hogs

[1] Eliot, "Trans. Amer. Association Obs. and Gynec.," Vol. I, p. 21.

[2] Chisholm, *The Medical Record*, Vol. XXXIII, p. 63.

only;[1] hen cholera, some members of the feathered tribe; the Southern cattle plague, cattle only; while the corn-stalk disease is only known to me to attack cattle—it certainly does not hogs, but may other herbivora.

Now, given the outbreak, well marked clinically, and in which we find the well-known microscopical lesions in a blood disease of this character (and I say it against the united and piled up authority of the whole ultra-bacteriological school) *if a competent microscopist finds in the blood and tissues of an animal killed, or which died and was opened in due time, one form of micro-organismal life, and no other, or even if in smear-preparations he does occasionally find some extraneous thing—I say that he does not know his business if he is not absolutely certain that that organism is the cause of the disease, experiment or not; cultures or not.*

For instance, our farmers do not need to be told when the Southern cattle plague is among their cattle. The first thing they at once discovered is that Texas cattle have been imported and driven, or have wandered about. That fact known, the season summer, cattle dying in numbers, with red urine, constipation and high fever—no other means are necessary to make a diagnosis. Those factors being present, we open such an animal—having killed it purposely, and under all precautions take away blood, pieces of organs, etc., and on making a microscopic examination of that material, we find but one organism present and that in great numbers—is there any actual need of experimentation to complete the diagnostic evidence? To my mind not.

During the past year I discovered an organism, without any knowledge of either of these necessary factors. Did I have any doubts that that organism, with which the blood was densely charged, was the cause of the disease which killed those animals, though I had no data by which to name it? I trow not.

Had I had such want of faith in my own judgment, had I so lacked in common-sense, I should be unworthy the position I occupy or reputation I enjoy? Taking, then, the reliability of the diagnosis into consideration, knowing the nature of the disease, and with perfect faith in the ability of these observers, who all say the material was from "undoubted cases of yellow fever," I am willing to risk some considerable reputation that the germ herein described, as present in all the material, is the specific cause of yellow fever, as well as that the description of the morpho-biological phenomena presented by the germ of the Southern cattle plague will largely be found applicable to this.

HEPATITIS WITH HEMERALOPIA. — Armstrong (New York *Medical Journal*) mentions a case of chronic interstitial hepatitis, with hemeralopia. The hepatitis was not discovered until the autopsy was made for there had been complete absence of ascites, œdema or icterus.

[1] In *Comptes Rendus*, Tome c. viii, a French observer asserts it comes naturally in sheep only, but there is room for an error there.

Hospital Notes.

MEDICO-CHIRURGICAL COLLEGE.

BLOOD STASIS.

WHEN an injured limb becomes boggy from blood stasis there is great value in supporting it with a compress bandage, and occasionally relieving congestion by numerous punctures in the integument of the part, rapidly made with a delicate, sharp-pointed knife. The rationale of this treatment is to induce absorption by compression, and to drain off surplus blood by means of numerous small punctures. Observance of this principle in all local congestions has, in my practice, made abscesses of rare occurrence. The old idea that a "bealing" should be allowed to come to a head is as fallacious as it is widespread. It is a morbid process the progress of which it is the duty of surgeons to stay.—*Pancoast.*

DACTYLITIS SYPHILITICA.

Shoemaker presented a case, which had been a bad one, perfectly cured, without losing even a finger nail. His treatment had been:

Internally, potassium iodide, grs. xx, and comp'd syrup of sarsaparilla, ʒij, ter in die.

Externally, was applied an ointment consisting of beta-naphthol, ℈j; unguentum citrinis, ʒss; ung. zinci. ox. benz., ʒj. The fingers were also painted once or twice a week with tr. iodine.

For irritable condition of intestinal tract, Shoemaker recommends silver nitrate, gr. viij; aquæ, ad. ʒiv; teaspoonful ter in die.

Skin diseases often owe their origin to some debilitated or irritable condition of the constitution, and are not due to local irritability only.

Seborrhœa sicca may become epithelioma by active degeneration.

For paræsthesia of the skin give local and central galvanism. It is purely a nervous trouble.

In applying the Brazilian bean (Jequirity) to epithelioma the application must be made on a raw surface, otherwise the use of the bean is of no avail.

—*Shoemaker.*

WHEN TO TREPHINE.

In compound fractures of the skull with depression, trephine as soon as reaction is establed. If depression exists to a dangerous degree, trephine at once.

In comminuted fractures, elevate and remove fragments of bone that become detached, and in doing so avoid, as far as possible, additional injuries to the meninges of the brain; but if the meninges are already divided, or should be torn in the removal of the fragments, suture them with fine catgut under antiseptic precautions.

In compound linear fractures, when splintering of the inner table is believed to exist, trephine.

In punctured fractures of the skull, trephine.

In localized paralysis following a fracture of the skull, trephine.

In trephining, use due care to avoid injuring the dura mater.

Use calomel freely in the after-treatment, to check inflammation of the brain.

In fractures of the base of the skull, surgical interference is rarely called for.—*Godfrey.*

AUTO-INTOXICATION.

A lady had been ill for several weeks with a low fever of anomalous form. There were no typhoid spots, the tongue was brown and uniformly coated, not small; there was no diarrhœa unless laxatives were given; when there was an undue amount of intestinal disturbance, but not so much as in typhoid. The temperature for the first few weeks was up to 102° in the morning and 103° in the evening; but quite often this was reversed, and there was a higher morning and lower evening temperature. After she had been ill some weeks the fever fell to about 100° and remained near that point for over a month. This occurred after the kitchen floor had been raised and some badly needed cleaning had been done. The stools were never of the typhoid type, but yellowish and very offensive. Her breath was also very bad. For these symptoms she was directed to take sulphocarbolate of zinc, three grains every four hours. Immediate improvement took place, in the disappearance of the bad breath and the fetor of the stools, and her general condition was improved. Still, she was not well. Her nurse called attention to the fact that the patient had a leucorrhœa, with an odor resembling that of her breath. Irrigations of the vagina were then employed, with the same antiseptic agent; using twenty grains to the pint of water. The improvement was manifested at once; the temperature sank to the normal and the patient's strength began at once to return. The symptoms related, together with the great depression of the patient, pointed to a septic condition of the blood; and the prompt relief following when the intestinal canal and the vagina were put in an aseptic condition confirm me in the belief that these were the sources from which the toxic agents were absorbed into the blood. This is also another instance of the efficiency of the sulphocarbolates as intestinal antiseptics. No other *harmless* antiseptic has proved as efficient for internal administration.—*Waugh.*

A Tonic Formula.—Flint (New York *Med. jour.*) considers this an excellent tonic formula, combining, as it does, all the important salts of the blood. For the sake of convenience the formula is put in the form of compressed tablets by Fraser & Co., Caswell, Massey & Co., N. Y., and in sugar-coated tablets by Warner & Imgard, 1322 Broadway, N. Y., all under the name of saline and chalybeate tonic:

R.—Sodii chloridi, C. P.	ʒiij.
Potassii chloridi, C. P.	gr. ix.
Potassii sulphatis, C. P.	gr. vj.
Potassii carb. (Squibb)	gr. iij.
Sodii carbonatis, C. P.	gr. xxxvj.
Magnes. carb	gr. iij.
Calc. phos. præcip	ʒss.
Calc. carb.	gr. iij.
Ferri redacti (Merck)	gr. xxvij.
Ferri carb.	gr. iij.

M.—In capsules, No. 60.

Sig.—Two capsules three times daily after eating.

Pamphlets.

School Life and its Influence on Sight, by G. T. Fox, M.D., Philadelphia.

Annual Announcement of Cooper Medical College, San Francisco, 1889.

Pathology and Treatment of Alopecia Areata, by A. R. Robinson, M.B., L.R.C.P. and S., New York.

This is an able and exhaustive paper, illustrated with a number of microscopical engravings, the whole showing careful thought and extensive research.

Disease of the Skin associated with Disorder of the Female Sexual Organs. By George, H. Rohé, M.D., Baltimore, Md. Professor of Dermatology and Hygiene in the College of Physicians and Surgeons, etc. Reprint from the *Buffalo Medical and Surgical Journal*, February, 1889. 13 pages.

Success and Failure of Electrolysis in Urethral Stricture, Especially Dr. Keyes' Method Reviewed, by Robert Newman, M.D.

Dr. Newman, the able apostle of urethral electrolysis, explains in his forcible style the reason of the failures reported, and the proper method to follow in order to gain success.

Melancholia in a Woman sixty-five. Recovery. By A. L. Hogdon, M.D., Baltimore.

Dr. Hogdon's patient. who by the way had decided to kill herself, recovered under the use of strong tonic treatment, and he takes occasion to say that he believes this kind of treatment is too often neglected.

Fifty-sixth Annual Report of the Managers of the Pennsylvania Institution for the Instruction of the Blind.

Diseased Conditions for which Sea-air is of Doubtful Benefit; and the Restorative Treatment of Sleeplessness from Brain Exhaustion, by Boardman Reed, M.D., Atlantic City, New Jersey.

Inebriate Asylums and their Work, by T. D. Crothers, M.D., Hartford, Conn.

This is a strong plea in favor of the belief that inebriety is a true disease of the mind, and should therefore be treated not by clerical anathemas or social ostracism, nor should even moral suasion be relied on; but such persons should be put in proper asylums, deprived of their liberty for a time, and treated with all the skill that medical science can command.

A New Principle in the Surgery of the Bladder, by Otis K. Newell, M.D., Assistant Demonstrator of Anatomy at the Harvard Medical School, Surgeon to Out-patients at the Mass. Gen. Hospital. Reprint from the Boston *Medical and Surgical Journal*, May 10, 1888, 20 pages.

Dr. Newell urges the adoption of sounds and catheters of a length not exceeding six inches, claiming that larger instruments are unnecessary. He then applies the same suggestion to the construction of evacuators in operations for stone.

Diagnosis of Tumors of the Bladder and Stone with the Cystoscope, by Otis K. Newell, M.D., Surgeon to Out-patients, Mass. General Hospital, Demonstrator of Anatomy, Harvard Medical School. Reprinted from Boston *Med. and Surgical Jonrnal*, April 18, 1888, 6 pages.

A neat little pamphlet showing what assistance in the diagnosis of vesical tumors and calculi may be derived from an exploratory examination of the organ by means of the cystoscope.

Hygiene for Home Missionaries, by E. Cutter, M.D., LL.D., New York.

In the way of drinks the writer advocates, especially for brain-workers, a pint or more of hot water before meals and before retiring. He says that ice water will not then be wished for, and likens the action of hot water on the body to that of oil on much used machinery. To have spring water, he says, compensates in a measure for the losses entailed by an absence from civilization; while hydrant water is "usually a botanical and zoölogical garden."

The Times and Register

A Weekly Journal of Medicine and Surgery.

New York and Philadelphia, June 22, 1889.

WILLIAM F. WAUGH, A.M., M.D., Editor.

REPRESENTING THE
PHILADELPHIA MEDICAL TIMES.
THE MEDICAL REGISTER.
THE DIETETIC GAZETTE.
THE POLYCLINIC.

PUBLISHED UNDER THE AUSPICES OF THE
AMERICAN MEDICAL PRESS ASSOCIATION.

Address all communications relating to Editorial or Subscription business to THE MEDICAL PRESS COMPANY, LIMITED, 1725 Arch Street, Philadelphia.

Address all communi ations relating to Advertising to THE MEDICAL PRESS COMPANY, LIMITED, 24 West 23d Street, New York.

THE POLYCLINIC.

WE take pleasure in announcing that The Medical Press Company, Limited, has purchased *The Polyclinic* from Messrs. P. Blakiston, Son & Co. The advertising and subscription contracts of *The Polyclinic* will be filled by THE TIMES AND REGISTER.

The Polyclinic has just completed its sixth volume. It has always maintained a high standard of literary and scientific merit, and has been able and impartial in its editorials. In recognition of these facts, and of the good work bestowed upon the journal by the gentlemen who have hitherto conducted it, we have decided to retain the title of the journal and place it at the head of our most valued departments. Henceforth our "Hospital Notes" will be entitled "The Polyclinic." This is peculiarly appropriate, as the records of that department are really gathered from "many clinics."

The former editor of *The Polyclinic*, Prof. Henry Leffmann, has consented to become a member of our editorial staff, the American Medical Press Association, and will assume charge of the Sanitary Notes and Toxicology. In this department will also appear such analyses as may interest the physician.

Dr. George M. Gould, whose work has been a feature of *The Polyclinic*, will continue the same for THE TIMES AND REGISTER.

We feel assured that the readers of all the journals concerned will profit by this union.

THE MEDICAL PRESS CO., Limited.

DR. WILLIAM F. WAUGH has secured apartments at *The Stoddart*, corner of Illinois and Pacific Avenues, in Atlantic City, where he will remain during July and August.

All correspondence concerning THE TIMES AND REGISTER should be directed as usual to Philadelphia.

THE doctors who made the autopsy on Bishop have been indicted for violation of the sanitary law.

THE SUMMER'S REST.

THERE is a theory extant that rest means simply a change of occupation. This is only in a certain sense true, and with important limitations. Labor is an expenditure of vital force, whether it is done with the brain or with the muscles, and the addition of exercise to the accustomed mental tasks means simply an increase of expenditure. Hawthorne, in his delightful story of Brook Farm, tells us that after swinging the scythe all day he and his companions found themselves inapt at literary labor, but preferred to lie upon their backs and ruminate. The professors of physical education will acknowledge that their best pupils, the stroke oar and the captain of the nine, do not shine in their classes, or even take a higher place because of their physical development.

This gives a satisfactory explanation for the fact that the prescription of exercise rarely does much good. Physical labor, taken without any other object than the exercise itself, soon becomes so irksome that no man has ever been known to persist in it very long. We have all smiled over th shrewd trick of Charles D. Meigs, who ordered his patient to take a daily walk out to Fairmount and drink a glass of water from the chalybeate spring. We venture the assertion that the wise old doctor told his patient to stop his work an hour sooner than usual in order to do it.

We may state our belief plainly, in the proposition that exercise is never rest when it is added to the tasks previously accomplished, but only when it is substituted for them. Besides this, the occupation thus substituted should be contrasted as markedly as possible with the toil which it substitutes. A literary man may find the study of philology a recreation when he is weary with his legal pursuits, but he had better saw wood.

Nobody earns a vacation better than the physician, and no one finds it so difficult to take. It is one consequence of the practitioner's active life, especially due to his having no stated time in which to do his work, but being in constant readiness to turn out at any hour, that he loses the capacity of resting. He sleeps with one ear open; he goes to church or to the opera with the guilty conscience that Mrs. Smith's messenger may tap him on the shoulder at any moment; and the apprehension of this interferes so much with his enjoyment that he loses all zest for the theater, and often forgets that he has a soul to be saved. If, however, his friends succeed in driving him off for a vacation, after sufficient time has elapsed for this expectancy to wear off, there is no one more companionable than the doctor. He is then like a boy out of school.

But we fear that many a vacation is wasted because one has forgotten how to rest. One of our colleagues, who is trying to bring his life to an early close by compressing into forty years the labors of seventy, must needs spend his vacation in writing a book.

Women do not require any rest; but when they invade a vacation resort, begin at once to impose upon it the laws of society, until a campaign at a watering place becomes more arduous than the winter's fashionable occupations from which they are supposed to be resting. Man, however, limiting the term in this case to the class which really works, unconsciously demonstrates the truth of our theory by seeking out the places where woman comes not, and comfort reigns. Better is a dinner of fried bacon and potatoes, with jack boots and flannels, and a bed of hemlock boughs, than the concoctions of a French chef, with dress suit and patent leathers made obligatory.

The physician who is fortunate enough to have a month at his disposal can obtain the greatest amount of benefit from it by adopting some such plan as this: Do not start out with the intention of doing or seeing any stated thing. Go to any secluded spot, Lehigh Gap, Eagle's Mere, or some unknown locality along the Allegheny range, where one can be genuinely lazy, sit about, sleep, listen to the talk of the natives, or idly saunter; where one's conscience cannot impose upon him the necessity of doing anything, because there is nothing to do. Do this until the desire for active exertion arises. Then, go wherever the impulse dictates, by tramping, preferably, unless a canal boat is available. This should be done without any special goal in view, stopping when tired, resuming the journey when rested. Such a trip takes one out of traveled paths into the byways. He is relieved of the task of seeing objects of interest, and of doing what is the correct thing to do. And he will bring home a store of experiences as miscellaneous and as highly prized as the contents of a boy's pockets, but not one of which could possibly be found in any guide book or tale of a traveler. It may be well to add that none but a truly lazy man would enjoy this mode of spending a vacation, and that it is not suited to the energetic rester who does London, Paris, and the Rhine in a month, including the time spent on the ocean.

Companions are objectionable in such an aimless ramble, as one might feel an impulse which is not shared by the other, and in that case some stress might be laid on the inclination, which would mar the symmetry of the rest. The only companion suitable to such a trip is a dog; one being preferred which would have decided personal objections to being stolen, and no backwardness in expressing them. Perhaps a geologist's or botanist's outfit, or an amateur photographer's traps, might be allowed to meet the exigencies of special cases; but the only things really essential are a soul truly appreciative of the beauties of repose, and the dog.

Dr. G. F. Prowell, of Burnside, Pa., says that carbolic acid, belladonna, and glycerin will abort whooping-cough with certainty.

Annotations.

[Copy.]

New York, May 5, 1889.

To Drs. G. E. Brewer & W. K. Otis.

Gentlemen: During our last pleasant interview, you expressed a desire to receive another letter from me, regarding the challenge you made to me, to test electrolysis *vs.* urethrotomy.

I can do no better than to confirm my former letter and correspondence, published in the Philadelphia *Medical Register*, March 30, and I again state, that to please you, I am ready for the contest, *if unfairness to either party is made impossible.*

Please communicate with Dr. J. V. Shoemaker, 1519 Walnut Street, Philadelphia, who has kindly consented to act as my representative. You have read his letter of April 8, in which he makes the propositions, which are rather against me, and more favorable to you; for instance: that you have the selection of two surgeons as a committee, while I have nothing to say about it. Nevertheless, I will agree to all Dr. Shoemaker may do, and am anxious to begin at once.

Believe me ever yours, most sincerely,

Robert Newman.

MOTHERS' MARKS.

SEVERAL choleric letters in the *Medical Age* show that some of its subscribers are at loggerheads over this never-to-be-decided subject. One doubter who asserts that there is no nervous connection between mother and fœtus, receives a caustic retort from a believer, who thinks he has annihilated the doubter by saying that if this learned man is so wise, perchance he can tell how many spermatozoa it takes to impregnate an ovum. Another believer cites these two cases in point:

"Mrs. S., in her third month of pregnancy, while crossing a meadow south of her residence, became frightened at a bull which gave chase to her. Six months later she gave birth to a child, a boy, who had a head shaped like the bull. This child lived to eighteen years of age and never spoke a word; when he wanted food he crawled upon his hands and knees and bellowed like a bull.

"A second case is as follows: Mrs. C. M., in her second month, while on her way to a well near the house, met a crawfish on the walk, became frightened, and seven months later gave birth to a girl baby. Both hands bore a marked resemblance to the two claws of the crawfish."

Such little instances as these are perfectly credible: they are reported almost every day; only it is strange that we never see them.

We can partly comprehend why a son should resemble his father; but the bull certainly took a very indirect method of transmitting his features to posterity, and we are inclined to think that his conduct was not justifiable.

In the second instance, the crawfish was evidently in the wrong. A crawfish old enough to walk out alone, should have been intelligent enough to recognize the woman's condition, and, fearful of the consequences, to hide itself until she had passed. The crawfish might then have continued its stroll with a light heart.

THE A. M. A. MEETING.

THIS number of the TIMES AND REGISTER will meet the American Medical Association at Newport. We trust that we may be mistaken in our prognosis, but we fear that the selection of this city will prove to have been a mistake. It is a beautiful little seaside resort, but has very few hotels, and no facilities for handling a crowd. The Association has got to be too big a thing for a place like Newport. How much better it would have been if Atlantic City had been chosen. It is essentially a city of hotels. It has the best of markets, is easily supplied, and it makes a business of handling crowds, to which the two thousand expected at Newport are but a trifle.

The Pacific slope delegates are endeavoring to have the next meeting in their section, but this does not seem to be probable. Philadelphia is also an aspirant for the honor, but until she can rise above the cliqueism which hopelessly divides her physicians she does not deserve it. Should the Association decide to come to the city of brotherly hatred, it would be the signal for an outbreak of hostilities, one faction endeavoring to capture the Association and the other to obtain its share of the honors. In Boston it would be much the same, only that the "clique" would comprise all of the city, and the Association would be organized on the principle of "*aut Boston aut nullus.*"

It is probable that a majority of the members would rather meet next year in New York City, and nowhere would they meet with a more cordial welcome.

One of the most interesting questions of the meeting is that of who shall direct the Journal of the Association. It seems to be settled that a Western man is to be chosen, and if this be the case, we know of no one who could fill the place more acceptably than the present editor of the American *Lancet*, and President of the American Academy of Medicine, Leartus Conner. But it would be difficult to say wherein the present management can be improved, unless by adopting the consolidation policy inaugurated by the TIMES AND REGISTER.

FRESH-AIR FUNDS.

MODERN beneficence does much to ameliorate the unhappy lot of the poor of our great cities. Perhaps nothing works more clearly the upward advance in the evolution of civilization than does the growing kindness of man towards man.

Only those who have visited the poorest quarters of such cities as New York, Philadelphia, and others can realize the utter wretchedness of the inhabitants' lives. They cannot all be made comfortable, but one day of gladness will give pleasant memories for months to follow. This and more is what the fresh-air fund does.

The New York Board of Health has formed a corps of fifty physicians, who will visit all the tenement houses, give medicine when needed, and distribute a few plain hygienic rules. They are also furnished with fresh-air excursion tickets, to be given away as they think best.

A NEW DANGER.

THE business of a physician is becoming rather dangerous in Kentucky, if we may believe a late paragraph concerning Louisville. It seems that two physicians failed to deliver a woman, either naturally or by instruments, and the patient died undelivered. The irate mother swore out a warrant charging the medical men with manslaughter, and they were both arrested.

If so unjust a proceeding as that receives any countenance from the law, matters will have reached a pretty pass.

If there is a charge to be made against a physician either for such neglect or for such ignorance as led to the patient's death, the coroner is the proper person to investigate the charge.

The doctor might leave the afflicted house along with the constable; since in spite of the fact that the mother advised using the medicine which the neighbor, Mrs. Brown, declared was a "sure cure," the physician had obstinately persisted in giving his own fatal drugs. And with what result? "he had killed her poor dear children."

A physician arrested is a physician disgraced, no matter whether the trial turns out for or against him; and we trust that the outcome of this case in Louisville will show a stern judicial frown upon this and any similar high-handed action.

Indeed, we ask, would not the ends of justice be more frequently attained were all testimony to be given in this way; without the frightening of witnesses by the apparent ferocity of clangorous attorneys; without swaying the jury by the emotional effects of fine periods, elocutionary efforts, oratorical appeals, and gesticulatory exercises; without obtunding their judgment by exhibitions of broken-hearted mothers, fainting wives or weeping children?

The ancient Egyptians managed much better. The testimony was all written down and given to the clerk. In the silence of a quiet and secluded court-room a bench of learned judges gravely listened to this evidence, read in the clerk's official voice; and then thoughtfully and intelligently gave their verdict.

A MEDICO-LEGAL CHAIR.

AT the late meeting of the Medico-Legal Congress a resolution was unanimously adopted, declaring that it was the duty of every college in which law or medicine is taught to have a chair of medical jurisprudence.

We heartily agree with this resolution, at least so far as it concerns medical colleges. If the opportunity of becoming acquainted with even a few of the cardinal principles governing medico-legal inquiries had been given to more of our physicians of the past and the present day, fewer painful court-room blunders would have been committed, resulting in the humiliation of the witness and disgrace to the profession at large.

In accordance with popular unreasonableness, it is expected of a medical man that he display in the witness box the same coolness and clearness of head and the same ease of manner that does the lawyer

who is cross-questioning, and whose daily business it is to deal with witnesses.

But though it is very rare for a non-legal man to become acclimated, as it were, to the witness box, a little instruction during student life in what to expect and to avoid, and on how to conduct themselves generally, would frequently enable medical men more nearly to do themselves justice.

THE TENNESSEE STATE BOARD.

THE Governor of Tennessee seems to be a man of particularly good sense. He is evidently aware of the fact that however much he may be acquainted with politics or the chicanery of the law, he is not versed in medicine, and is therefore loth, and properly, to rely on his judgment, which is likely to be incompetent in matters pertaining to that especial branch of knowledge. The State of Tennessee has lately passed a law establishing a medical examining board of four, and the Governor with exceptional courtesy and sense asked the State Medical Society, while in session, to recommend three physicians for appointment as examiners, he reserving the right to appoint the fourth regular practitioner.

The State Medical Society has, therefore, practically the privilege of electing the board of examiners, and a board thus chosen by a society composed of the representative physicians from over the whole State is more likely to prove a satisfactory one, than if it were appointed by one man or elected by political machinery.

Letters to the Editor.

ANTIFEBRIN IN NEURALGIA AND GONORRHŒA.

CASE I.—Jno. S., came to me with following history: Strong, robust man, aged twenty-eight; appetite good, habits regular, occupation carter. Has had intense pain over either right or left brow or right or left parietal region. This pain always came on in the arm, about half an hour after arising, and about the time he was ready to start he was suffering with an intense pain, from which he could obtain only temporary relief by frequent calls at the various drug-stores on his route. This pain would continue with increasing severity until about 11 A.M., when it gradually subsided, and from 2 P.M. until the next morning he would be free. During all this time he slept well, bowels regular; and the above symptoms have been going on for three weeks, until he came to me with his case. I prepared one powder

Morph. sulph.	gr. ⅙.
Antifebrin	gr. viij.
Sacch. alb.	gr. viij.

with instructions to take it in water a half an hour after arising, and to report result in twenty-four hours. I did not see him for three days, when he came in smiling saying, "Doctor, that stuff you gave me was boss; I have never had a pain since."

CASE II.—Geo. H., came to see me a week after first case; with history of constant pains, fugitive, running up one side of the head, at other times over the occipital region, and then through frontal, facial, and maxillary bones; he seemed almost beside himself with pain. I immediately gave him the same dose in water, and inside of seven minutes he began to feel relief, and in ten all pain had left.

I cite the above two cases to show what the combination will do. In all ordinary neuralgias, I give eight grains antifebrin, dissolved in tr. aurantii, and syr. simp. with the most gratifying results. I put out about forty powders a week on an average.

This week, I met a case of gonorrhœa at the middle of the first stage, with profuse discharge and ardor urinæ. Ordered the urethra washed out with hot water after urinating, and immediately the following injection. Don't smile, but try:

Antifebrin	gr. x.
Bis. subnit.	gr. x.
Aq. font.	℥j.

Sig.—Inject after urinating ℥j four times a day.

and see if your patient will not exclaim with mine: "Doctor, you got there; the running has all stopped and pain all gone." GEO. W. COX.

ANTIFEBRIN.

UNDER the interrogative heading, "Is antifebrin dangerous?" Dr. A. L. Saylor reports in THE TIMES AND REGISTER a case within his experience in which he gave to a child four years of age, with a temperature of 101° to 103°, four grains of antifebrin. An hour afterwards alarming symptoms of collapse set in with a subnormal temperature. The patient was, however, revived by means of restoratives and recovered.

I can report a similar case in that of a girl fifteen years of age in the second week of typhoid fever. The temperature having risen above 104°, I gave five grains of antifebrin and left two more five-grain powders to be administered an hour apart, my intention being to return before the third was taken, to observe the effect. Soon after the second dose had been taken I was summoned by a messenger, who said the girl was dying. I found the patient very weak, with cold extremities, a fluttering pulse, and a subnormal temperature. Hypodermics of brandy soon revived her, and without any more antipyresis she subsequently recovered from her illness. I reported this case when the subject of antifebrin came up before the Providence Medical Association, and several cases were mentioned by others, but I have not yet heard of one which resulted fatally. However, since these alarming symptoms not uncommonly occur, we should be cautious in exhibiting antifebrin or antipyrin until the idiosyncrasy of the patient, if one exists, has been ascertained. It seems to me that four grains of antifebrin to begin with is decidedly too large a dose for a three-year-old child. I will also state that I cannot see the indication for antipyretics in a case with a temperature of 101° to 103°. I can well remember Prof. Loomis' manner—which he could always make impressive enough to linger in the memory—when he asked while lecturing on scarlet fever: "Shall we use antipyretics if

the temperature is 105°? No, for scarlet fever patients bear a temperature of 105° easily." In other words, the fever, uncomplicated, soon runs its course or *burns out.*

There is little doubt that the antipyretic craze will eventually do damage to the virtue of antipyretics themselves, if it has not already done so. If we cover a fire with ashes, it will smoulder slowly; or if we throw water upon it at intervals without extinguishing it, the combustion, though retarded, will be none the less sure, and not a particle less heat will be evolved or energy utilized. This is crude reasoning, but I think it has a foundation. We may soon expect that the pendulum of opinion will begin to swing the other way, and numerous papers will be published discussing the question whether or not antipyretics prolong the duration of fevers. After a little more swinging of the pendulum conservatism will find for these valuable agents their proper place in therapeutics.

E. W. PENNEY, M.D.
PROVIDENCE, R. I.

ANTAGONISM OF FORCES.

IN *The Medical Register* of March 5, 1886, I wrote an article under the above heading. On April 20, 1888, Sir William R. Grove, F.R.S., delivered a lecture at the Royal Institute of Great Britain on the same subject, taking precisely the same views that I advanced. The lecture was published in *Nature*, and republished in the September number of the *Popular Science Monthly.* The learned Judge was more prolific in his illustrations showing the law to be general throughout the universe than I was, for want of space when writing for a medical journal. But he did not attempt any practical application of it as I did. It is evident that he never read the article I wrote. He stated that he was not aware that this law of antagonism had ever been presented to the world before his lecture, and that he did not question but it would become as universally recognized as the law of gravity. This encouragement induces me to present other thoughts on the application of the law, which I have for some time been considering.

When Jenner inserted in the boy's arm the vaccine matter, he acted upon the theory of antagonism. He inserted a microörganism, which was either directly antagonistic to the smallpox germ, or else generated matter inimical to that which smallpox itself produces.

A man long residing in Cuba builds up in his system a more effectual preventive to the yellow fever, than a Memphian who has had the fever in his native town. The Cubans say they do not wish the yellow fever driven from their island, for that for every Cuban it kills, a thousand Spanish soldiers die of it.

In my essay of March, 1886, I suggested that the yellow fever develops and leaves in every city it attacks, upon the houses, the trees, and all objects that harbored the fever germs, an antagonism to the fever, just the same as it does in an individual whom it has attacked. In evidence of this, I noticed that the yellow fever rarely travels the same route in its successive ravages—that at one time it riots in the West Mississippi Valley; the next in the East Mississippi Valley; and then upon the Atlantic coast. In 1888, the fever followed the rule; and that even when it broke out in Jackson, Miss., it did not spread. I doubt whether the fever in 1888 could have been made epidemic in any of the places it visited in 1878, or even in the East Mississippi Valley; for in 1878–9 in all probability the antagonism that was engendered spread much more generally and extensively than the fever did. According to analogy and the history of the fever, the longer it remains away from a place, the more readily and violently it takes hold when it returns.

We are searching for the antagonism. Is it a living microbe, or some matter poisonous to the germs of disease? If it were the latter, it would likely be as poisonous to one species of microbe as to another. Sulphur is poisonous to every species of insect. Carnivorous insects devour only certain kinds. Parasites both animal and vegetable make choice of certain species for their home. It seems more probable that the antagonism is a living force, a parasite, a devourer, a microbe.

In the healthy human system microbes are generally found. What good or harm they do has not been determined. Possibly they may be the antagonism that drove out the measles or some other contagion—we are in a wide field of thought. When giving a medicine poisonous to the microbes of any disease, may the treatment not also destroy some antagonism to that or some other affliction? Quinine is considered one of the best of microbicides, especially of malarial microbes; yet chills are more likely to return after a quinine cure than after that of any other treatment. It looks as if the quinine, while destroying the malaria microbes, destroys also the antimalaria microbes. The patient is left free of any internal antidote to chills, and of course takes ill again on any slight contact with malaria. It is hardly safe to say, "If a medicine will do you no good, it will do you no harm." We do not know what valuble antagonism it may destroy.

It is well known that an epidemic, after it has raged for a while in any place, becomes milder and milder till it dies out. To say its antagonism becomes stronger and stronger would, perhaps, be the truth. Pasteur has clearly proven that the microbes of any contagion, as chicken cholera, may be cultivated until when administered they will hardly affect the fowl. A chicken thus treated is safe from another attack of the cholera. The waning power of an epidemic and that of Pasteur's cultivated microbes are similar, and doubtless due to the same cause. I am of opinion that Pasteur in cultivating the microbes cultivates with them an antagonism, and that this antagonism being given at the same time as the cholera microbes modifies the disease. No animal or vegetable weakens or becomes extinct or useless by some antagonism. Now, is it possible to get the antagonism free from the disease, and give that to the chickens? If so, it will mark one of the very grandest triumphs of medical science. Has M. Pasteur or any other person ever continued to cultivate

the chicken cholera microbes in an emulsion till the microbes would disappear, and till it would fail to make the chickens sick, and then tested its power to prevent an attack of the cholera? A chicken having recovered from the cholera is possessed of an antagonism to that disease. Now, if its blood be injected into the veins of another chicken, will the antagonism be communicated to the second chicken? If the antagonism is in such blood, can it be cultivated and multiplied like the microbes of the disease and then communicated to other chickens sufficiently to prevent them from having the cholera? Here is a wide field for experiment with all microbic affections and antagonisms.

It does seem to me that there is a strong probability of getting the antimicrobe matter free of a contagion by communicating this to prevent the contagion. Pasteur is satisfied that fatality from rabies and all other contagions can be successfully inoculated against by using a solution containing degenerate microbes. He has not yet carried his tests far enough to verify the ideas here introduced. By cultivating the rabies microbes until the antagonism becomes strong enough to destroy the microbes, and then continuing the cultivation of the antagonism, may not enough of it be thus generated to inoculate all the dogs in any country and thus free the people from the dread malady of hydrophobia?

There is, however, one suspicious difficulty. Can the antagonism survive a sufficient length of time after the destruction of the microbes of contagion? Will the anti-microbic perish when it has destroyed the microbes? In an individual the antagonism to the return of a contagion lasts for life, but that left in a city becomes too weak in the course of time to present a return of the epidemic.

The microbe is only an infinitesimal form of life, and, so far as studied, it is subject to all the laws of lower life. Insects of one species devour those of another, and are devoured themselves in turn. Birds eat them in both the fly and in the worm state; moles and mice fatten on them; buried in the chrysalis state, beetles feast on their eggs; parasites live upon their bodies, and microbes devour them from within. They have many antagonisms besides the heat of summer and the frost of winter and poisonous plants.

The ordinary cut worm, the honey moth, the ant, the bee, are able to maintain themselves at nearly even rates each year. They belong to the well-balanced forces in nature. The army worm, the cotton worm, the Rocky Mountain locust come by floods, do terrible work, and then disappear altogether. When they come, doubtless all their enemies fatten and rapidly multiply, especially the microbes that devour them within, as is certainly the case with the Rocky Mountain locust—for it becomes afflicted with a deadly plague. The sections which these floods of insects devoured will not sustain the same insects for years afterwards; for the microbes that destroyed them remain there for a long while. Malarial and typhoid fevers resemble the balanced forces; the cholera and yellow fever resemble those that come by storms and floods. Who can tell but that the microbes of an epidemic become themselves infested with still smaller microbes, or by parasites that devour them externally, and that when these destroy the epidemic germs they continue to live in the patient a harmless life, and forever afterwards protect the person against another attack of the epidemic; or that they flourish throughout the whole city for years afterwards to prevent a return of the plague.

To say that a microbe is too small to be infested with other microbes is only to acknowledge that our imagination is limited by our experience. Many parasites may live on or in any object that can be seen with a microscope. In a human body swarming with smallpox microbes, what is it that destroys them or drives them out of the body? There is a war in that body. The microbes will either devour the body or the anti-microbes will destroy the microbes.

Plagues among cattle are much more numerous and destructive than among men, among insects than cattle, and, perhaps, among microbes than insects. In the 70's most of the United States was afflicted with caterpillars. They were a plague themselves, and they never would have left us had not a plague of microbes destroyed them. Microbes are only parasites, and these are "insects living on or in animals or other insects." Antagonisms are still other parasites destroying these pests. In fact, herbivorous and carnivorous animals are no exception to the rule. The fox is a plague to the poultry and the dog is antagonism; both alike destructive, one to the chicken, the other to the fox. The whole earth and the universe is moving and oscillating under the same law, and all the living things therein are struggling for life and protection under this law of antagonism.

E. H. RANDLE.

JACKSON, TENN.

NOTE.—Since, in the next twenty years, the varied species of bacteria will give us a burdensome nomenclature of unpronounceable and unrememberable Greek and Latin names, we suggest the plan we have followed in this essay be adopted. Let microbe be the generic name, and the specific name be the same as that of the disease, thus, the cholera microbe, the yellow fever microbe, and so on. Everyone will understand such a nomenclature as this without having to learn it.

E. H. R.

HIGHER MEDICAL EDUCATION.

I DESIRE to brifly notice Dr. Snyder's excellent article on Higher Medical Education, which appeared in a previous issue of THE TIMES AND REGISTER. There can be no question that the standard of education preliminary to the study of medicine should be raised; but how much? There are extremes here as in all other important questions, and there is great danger from this very cause. To place the standard too high would be almost as disastrous to the profession as too low a standard. The doctor suggests a classical education. That is very good for all who are fortunate enough to obtain such an excellent training; and if it were within the reach of all our young men I would say amen. In looking over the history of the past we find that there were at the head of all professions men whose early train-

ing had been neglected, or men whose poverty forced them into their chosen professions before the desirable preliminary education could be obtained.

These men were, many of them, farmers' or mechanics' sons, who had formed sober and industrious habits on the farm or in the shop, and whose physical development was of the most perfect kind. These ambitious young men with their extraordinary powers of endurance, their, in many instances, great natural abilities, with only a common school education, made their way to the front in times past, and I presume they will continue to do so for all time to come, unless they are forced out of the race by barriers which will prevent them from making the start. I wish to make the statement right here, that all the doctors who fail, or who become quacks, do not belong to the class who started in life with a limited education. It is not an unusual thing for a young man with only the elements of a common English education to pass by and beyond his classically educated brother. Having these facts before us, we should be careful how we bar intelligent young men who are fairly well educated out of the profession. A serious objection to a very high standard is that it is liable to keep the hard working poor young man out of the profession and open the way for the less industrious son of the wealthy man, and it seems to me that the tendency of this policy would be to sap the foundation of our boasted Republican form of government and result in the creation of an aristocracy. The greatest argument in favor of a classical education is, that it thoroughly disciplines the mind. If this be true, then the same argument stands good in regard to the mental discipline acquired by a thorough medical education. Is there any course of study better calculated to discipline the mind than an extended course—say four years—in medicine? If the mind has been well trained the individual can pursue any studies he desires to, and thus make up deficiencies after he has taken his degree in medicine. Who could estimate the loss to mankind if men had been required to have been classical scholars before entering the professions in the days of John Hunter—who surpassed his brother William, a thorough scholar—and A. Lincoln, and a thousand others eminent in their different callings, and some of whom never even attended a common school? Then do not build the barriers too high, but rather let a teacher's certificate of the first grade, common sense, honesty, industry, and sobriety be the standard requisite for the admission of our young men to our medical colleges.

EATON, ILL. C. BARLOW.

The Inquirer.

DIABETES FROM INJURY.

IN THE TIMES AND REGISTER of June 1, J. A. W. thinks that G. W. C.'s case of diabetes, if it followed injury, should be recorded. I saw a few years ago a case in which diabetes followed a fall while skating, the patient, a healthy lad, striking heavily on the occiput. The diagnosis was clear, and the termination fatal. D. G. LUCE, M.D.

SPRAGUE'S MILLS, ME.

Book Reviews.

ELECTRICITY IN FACIAL BLEMISHES. By PLYM. S. HAYES, A.M., M.D. Chicago: W. T. Keener, 1889. Pp. 128.

The author gives, in a plain, readable manner, the results of a wide experience in this important application of electricity. He devotes one chapter to the histology of the skin and hair, with especial reference to those peculiarities affecting the use and value of electricity. A chapter on necessary apparatus follows, another on mode of operating, one on nævi and other facial blemishes, and finally a short chapter of "donts." The author speaks freely on the failures as well as the successes to be expected, and altogether makes the little book a valuable aid to any one desiring information as to the method of using electricity for this particular purpose.

A MANUAL OF DISEASES OF THE EAR. By ALBERT H. BUCK, M.D. New York: William Wood & Co. Pp. 420. Illustrated. Price, $2.50.

This book is written for the use of students and practitioners of medicine by one who has had an experience for many years as Clinical Professor of the Diseases of the Ear in the College of Physicians and Surgeons of New York City; and although some years have elapsed since the publication of his first edition, this one shows very great change and improvement from larger experience in his practice and studies, which have naturally come before him in that time. It is a most excellent manual, its theories and treatment fully up to the knowledge of the specialists of the present day. It is well illustrated, and a very excellent and handy book for all. We recommend it with pleasure to the profession and students.

ATLAS OF VENEREAL AND SKIN DISEASES. With original text by PRINCE A. MORROW, A.M., M.D. Fasciculus XIV, Plate LXVI, lupus erythematosus and l. vulgaris; Plate LXVII, lupus papillaris, tuberculosis papillomatosa cutis; Plate LXVIII, sarcoma of trunk face, and chest; Plate LXIX, epithelioma, rodent ulcer; Plate LXX, tubercular leprosy showing macular lesions, tubercular leprosy. Fasciculus XV. Plate LXXI, scabies; Plate LXXII, pediculosis corporis; Plate LXXIII, chromophytosis; Plate LXXIV, tricophytosis and favus; Plate LXXV, eczema marginatum, favus. New York: William Wood & Co. 1889.

The most noteworthy characteristic of the concluding plates of this valuable series, besides their general excellence, is that the author has given us pictures of the eruptions due to the parasites instead of microscopic representations of the causative organisms.

Taken as a whole, this series is creditable alike to the publishers and to Dr. Morrow. From the standpoint of the general practitioner our principal criticism is that the plates represent the most strongly marked types of the respective diseases. If it were possible to supplement these by a series taken from cases of the same affections in their earlier stages, the value of the latter as aids to diagnosis would be very great.

THE INSANE IN FOREIGN COUNTRIES. By WILLIAM P. LETCHWORTH, President of the New York State Board of Charities. New York and London: G. P. Putnam's Sons, 1889. 8vo., pp. 374.

This book is a record of the observations made during seven months spent in investigating the asylums of Europe, especially those designed for the insane poor. The author states that his aim has been to ascertain the most advanced, humane, and economical methods of caring for the insane. He testifies to the courteous reception accorded him invariably by asylum officials, and the generous spirit shown in furthering his investigations. To those who are not familiar with the great establishments like that of Gheel, the book will be found of singular interest. The author is not writing as a physician, but as a keen-sighted man of the world.

A HANDBOOK OF THERAPEUTICS. By SYDNEY RINGER, M.D. New York; William Wood & Co., 1889. Twelfth Edition. 8vo. pp. 524.

The leading feature of Prof. Ringer's book is its practical character, the work being, in truth, as the author claims, a treatise on clinical therapeutics. In this it offers a marked contrast to Wood's "Therapeutics," which is essentially a record of the results obtained by physiological experiment. Ringer writes for the active practitioner; Wood, for the cultivated scholar, whose interest in matters medical is theoretical. He who is compelled to earn his bread by professional work should choose Ringer, and if he is able to add the other at a later period he will find a satisfaction in perusing it which he would not experience if he were to take it as his guide in practice.

The encroachments upon the field of practice which have characterized the later works on therapy are seen in Ringer's book, where the opening chapters are devoted to the consideration of the tongue, pulse, etc. This is not a good feature, as tending to useless amplification.

MATERIA MEDICA AND THERAPEUTICS FOR PHYSICIANS AND STUDENTS. By JOHN B. BIDDLE, M.D. Eleventh edition, revised and enlarged, with special reference to Therapeutics and to the Physiological Action of Medicines. By Clement Biddle, M.D., U. S. Navy, and Henry Morris, M.D. Philadelphia: P. Blakiston, Son & Co., 1889. 8vo., pp. 707; cloth. Price, $4.25.

The text-book of the late Prof. Biddle is too well known to require extended notice. The revisers have left out a good deal of useless matter, such as cuts representing parts of plants, and might have left out more. They have attempted to keep up with the march of modern therapy by introducing the newer agents; though the reader of medical periodicals would not be apt to say that the attempt is successful, when neither phenacetine nor sulphonal receive mention, and antipyrin is called a "succedaneum to morphine." The want of an index of diseases puts this work at a disadvantage as compared with its competitors. Indeed, we are surprised that this deficiency has not been remedied by an editor as capable as Henry Morris. It is also a mistake to prepare a book for both students and practitioners. The needs are as diverse as those of a primary school and a university. The student's text-book cannot be too rudimentary; the practitioner's too cyclopædic. Tht more this distinction is kept in mind the easier it is to impress upon the student that his college course is but the introduction to medical science.

Gleanings.

VALK (New York *Medical Record*) reports a case of fatty degeneration of the vitreous body.

KEYES (New York *Medical Record*) does not believe that a fibrous structure is ever radically cured by dilatation.

LENNOX (Brooklyn *Medical Journal*) contributes an exhaustive paper on the development of the crystalline lens, illustrated by thirty-one good microscopical drawings.

RARE DISLOCATIONS.—Stimson (New York *Medical Journal*) reports two cases of rare dislocation: one of the lower end of the ulna forward, the other being a dislocation of the upper end of the fibula outward and forward.

GLUT OF ORANGES.—It is estimated that in ten years Florida will produce a box of oranges for every inhabitant in the United States. The *American Analyst* suggests that this ought to inspire caution in those about to invest in orange groves.

MATAS (New Orleans *Med. and Surgical Journal*) gives in full the history of an interesting case of multiple subperiosteal sarcoma of the skull, associated with necrosis of the vertical plate of the frontal; with extirpation of necrotic plate and tumors, and recovery.

OTITIS MEDIA.—According to Hay (New York *Medical Journal*) otitis media is treated by Prof. Schwartze, of Halle, not by the dry method, but by syringing through the Eustachian tube with a mild solution of common salt. Schwartze believes that the dry method sometimes causes mastoid disease by blocking the outlet.

If the membrane is not already perforated, a puncture is made through the posterior inferior quadrant, through which the wash can run that is syringed into the Eustachian tube.

TREATMENT OF ASTHMA.—N. S. Davis (*Journal of the American Medical Association*) says that he frequently employs with benefit in cases of asthma with rather constant dyspnœa accompanied by tracheitis, laryngitis or bronchitis, this formula:

℞.—Chloral	grms.	15.00
Ammonii muriat.	grms.	10.00
Morphinæ muriat.	grms.	.20
Antimon. et pot. tart.	grms.	.15
Ext. grindeliæ robustæ fl.	grms.	45 vel 60.00
Aq. vel syr. glycyrrhizæ, q. s. ad.	grms.	120.00

Sig.—One teaspoonful every three to six hours in sweetened water.

Divulsion of Pylorus.—Kinnicut (New York *Medical Record*) reports a case of cicatricial stenosis of the pylorus relieved by digital divulsion.

Iodol in Otorrhœa.—Stetter says that acute purulent otorrhœa is rapidly benefited or cured by insufflations of iodol, though in chronic affections of this kind, quite varying results were obtained. The only objection to it—coarseness—has now been overcome by Merck, who has made it into a sufficiently fine powder.

Signs of the Moribund Condition.—Shrady (New York *Medical Record*), in writing on the above topic, gives these as some of the signs: Suppression of the catamenia, colliquative diarrhœa, pallid optic disk, abnormal appetite, optical delusions, intermittent pulse, left unilateral dropsy beginning in one foot, conjoined with coldness of ears, nose, malar regions, continued temperature of 105° F., coma, respirations thrice the normal, Cheyne-Stokes respiration. But one sign which he considers most reliable is an up and down movement of the pomum adami, provided this movement is persistent.

The Cure of Consumption.—The well-known fact that the tubercle bacillus can be cultivated outside the living body, thriving best at 37.50° C. (99.50° F.), and that it dies at 4° above or below this temperature, is valueless as regards the living body, because the nutrient soil is kept at an equable warmth by the constantly circulating blood. To maintain the blood temperature permanently at about 41° C. (105.80° F.) is impossible, and would kill the patient. Even the bacilli in tuberculous pharyngeal ulcers are not killed, though directly exposed for hours to the action of dry air at 150° C. (302° F.) Bacillary consumptives with a subnormal temperature of 30° C. (86° F.) are hopelessly and quickly destroyed by the rapidly multiplying bacilli. Workmen employed in porcelain and limekilns at 80° (176° F.) are just as liable to contract bacillary phthisis as others. An actual heating of the expired air while inspiring at the now fashionable hot-air apparatus is not proven. The thermometer does not indicate a difference of temperature between the expired air of the man who for one hour has inspired air at 150° C., and that of the one who has not done so. If the bulb of the thermometer is held in the mouth in such a manner that the inspiration current of hot air will strike it, the column will rise to 45° C. and beyond; but if the bulb be so held that the inspired hot-air current does not strike it, the column will rise only ½°–1° C., consequently the temperature in the lungs can be no higher. If the dry air in a lime-kiln at 66° be inhaled for ten minutes, the exhaled air remains at 37.50–38° C.

That the *heat* of hot-air inhalations shall have a devitalizing effect upon the bacilli in the lungs, as is asserted by several physicians of their newly invented apparatus, is threfore incorrect. My own method of dry, warm nitrogen gas inhalation, practised since thirteen years ago, has always shown that heat is quite an immaterial factor in the destruction of the bacilli; that it is rather an unnecessary infliction of cruelty, and that it has the same hurtful influence as have the tiresome exertions while breathing at the imperfectly constructed apparatus. The usefulness of hot-air inhalations consists solely in its influence upon the characteristically inflamed areas in the lungs and upon the catarrhal inflammation of the bronchi, whereby cough and expectoration are favorably acted on. Should this not occur in eight days' time, the proceeding had better be entirely suspended. Woe unto him who forcibly seeks to attain more! He certainly will furnish all the more corpses for the undertaker to bury.

My bacillary patients are treated in isolated cabinets by breathing an atmosphere deprived of oxygen to the extent of 3–5 per cent. The air breathed is rendered thus poorer in oxygen by diluting it to the requisite degree with nitrogen gas. The cabinets are not freed from atmospheric pressure. The nitrogen is generated in steel retorts at a temperature of 1000° C. (1832° F.), therefore absolutely dry, and when sufficiently cooled, inhaled. Is it desirable to breathe hot air, the patient inhales through a tube near the retort oven. Aside from the known *modus operandi* of nitrogen inhalation, which renders superfluous every kind of pneumatic treatment, the importance consists in the effect produced by the breathing of absolutely dry and diluted air continued daily for about four hours at a sitting. Does this directly kill the bacilli? It can scarcely be believed that they are at all disturbed. It is true that at dry altitudes of 15,000 feet the bacilli are killed, and the phthisis is cured, but not because they are made in any way uncomfortable by the rarified pure and dry air. Rarified air is not the important factor, therefore I do not work with a pneumatic apparatus. It is my belief that by means of the relative drying out of the tissues, in connection with somewhat diminished atmospheric pressure during the inhalation, the white blood corpuscles are enabled to migrate the more easily and, in larger number reach the bacilli in force and annihilate them. Phthisis is cured therefore, not by the annihilation of the bacilli by means of the direct action of hot, dry, rarified and diluted air, but by giving support to the cellular elements preformed for that purpose.

Besides general weakness, a small heart, attenuated bloodvessel walls, the hereditary tendency of consumption consists in the liability to the formation of small, circumscribed characteristic inflammations in the lungs, just as a liability to desquamative, watery, itching skin eruptions is congenital. The inhaled bacillus preferably adheres to and flourishes upon such areas. We also see that arsenic and tar preparations, like creasote, act most favorably in phthisis, as they do in skin eruptions. It is the *nutritive soil* of the bacillus that must be acted upon in order to attain results; this is accomplished by the use of an atmosphere rendered absolutely dry at a heat of 1000° C., considerably rarified, and deprived of oxygen to the extent of 3 per cent. by diluting with nitrogen. It is inhaled at a temperature of 16–30°C. (60.80–86° F.). —Dr. Steinbrueck, Halle,

Deutsche Medizinal Zeitung, No. 41, May 23, 1889.

According to *Merck's Bulletin*, thalline and thallium are frequently confounded even by those in high repute. Pure thalline is an oily fluid, but it is used only in the form of the salts—sulphate, tartrate. The thalline salts are used as antipyretics, antiseptics, and antizymotics. Thalline is also attracting considerable attention in gonorrhœa, used as an injection in a strength of from 1½ to 2 per cent. aqueous solution. Thallium, on the other hand, is a metal obtained as a side product from copper and iron ores. Its salts are highly poisonous, and so far as known they have been used therapeutically but once. These experiments by Pozzi and Courtade seemed to show that thallium has value as an alterative and antisyphilitic, but also that it is liable to produce alarming gastric spasms, vomiting, and stomatitis.

Length of Labor.—Price (*American Practitioner and News*) thinks that the question as to how long labor should continue "must be solved at the bedside; not as an old medical friend of mine was in the habit of doing, by waiting and hoping, by sympathizing and weeping with the suffering patient and anxious friends, and praying the good Lord to hasten delivery, but by applying the forceps and completing delivery before the vagina becomes hot and dry, and before exhaustion supervenes. Do not wait and hope till tired nature is no longer able to render assistance, and till the patient is on the brink ready to pass over the river into the life beyond. The forceps, properly and wisely used, save many a mother and preserve the life of many a child."

Hindu Pathology.—Bayu, Pitta, Kapha may be called the trinity of Hindu medicine. They are elements or humors—air, bile, and phlegm—principles of life and movement which guide and govern the human system.

In pathology these principles are as potent and exhaustive as in physiology. "When our *bayu*, *pitta*, and *kapha* are in equilibrium, our health is perfectly sound, but when any one or two or all of them are eccentric, our system is diseased. So also the eccentricity of any one of them may result in the eccentricity of another, or of all of them. When all the humors are at the same time eccentric, the resulting disease is called *sinnipata* or combination, and is looked upon as most serious." Certain symptoms indicate these eccentricies, and particular diseases are classed as *bayu*, *pitta*, or *kapha* diseases, *bayu-pitta*, *bayu-kapha*, *pitta-kapha*, or *sannipata* d seases. Particular diseases known by special names are referred to these classes for purposes of diagnosis and treatment. "The Hindu science of medicine attempts to treat a disease more by having regard to symptoms as they indicate the preponderance of *bayu*, *pitta*, or *kapha* in it than by having reference to the nosology for all its particulars." Therapeutics follow a similar rule. "Drugs are called *bayu-nasak*, *pitta-nasak*, or *kapha-nasak*, accordingly as they contribute to make *bayu*, *pitta*, or *kapha* eccentric." Cold aggravates and heat soothes *bayu* and *kapha;* while the opposite is the effect of these agents on *pitta*. Finally, these three principles have diurnal and seasonal influences—one or other being predominant at particular times of the day or year.

Such is a brief but complete view of the anatomy, physiology, pathology, and therapeutics of Hindu medicine. On coming face to face with a disease, the *modus operandi* of the *Kaviraj* is somewhat as follows: He squats down and examines his patient's symptoms—his pulse, his tongue, his eye, his urine, and so forth, and from his observations he settles in his mind whether the *bayu*, *pitta*, or *kapha*, one or two, or all, are "eccentric," and then he fixes on some formulary for which he possesses a Sanskrit sloka of Charak's, and applies it. The whole thing is a kind of practice by formula—resembling the *similia similibus* of the homœopathist. Deny the formula and the whole system crumbles. Admit the formula, and the rest is easy. The permutations of three words are not very numerous, and the memory can easily carry a Sanskrit sloka to suit each permutation. A knowledge of the structure and functions of the body, the nature of disease, the action of drugs—physiology, pathology, and therapeutics—is unnecessary. Give the principle and the sign, and the application is simple and certain.—*Indian Medical Gazette.*

The Local Use of Iodoform in the treatment of Chronic Cystitis.—Dr Ludwig Frey, of the Royal Imperial Hospital, Wien (Vienna), thinks he does not go too far when he says that nowhere else is the antizymotic power of iodoform more brilliantly displayed than by its use in chronic inflammations of the bladder, diseased conditions caused by the processes of decomposition. The most horrible and disgusting forms of chronic cystitis, no matter how far advanced or by whatsoever caused (prostatic hypertrophy, strictures of the urethra of gonorrhœal origin, lithotripsy, carcinoma and tuberculosis of the bladder, affections of the spinal cord etc.) are either cured or materially improved by its use. Besides its antiseptic and deodorising power, it possesses two other properties, styptic and analgesic, of incalculable value particularly in the treatment of vesical cancer. The bladder is thoroughly washed out with lukewarm, pure water, whereupon the liquid containing the iodoform is injected and the catheter withdrawn. The injection fluid is prepared by adding of the following emulsion:

℞.—Iodoformi 50.00
Glycerini 40.00
Aquæ destillatæ 10.00
Gummi tragacanthæ . . . . . 0 25—M.

Sig.—A tablespoonful to one-half liter of warm water, well stirred up.

These injections are repeated every third day. As a rule after the third or fourth injection the improvement has so far advanced, that one treatment per week will be sufficient.

—*Wiener Medizinische Presse*, No. 20, May 19, 1889.

TOBACCO smoke is something of an antiseptic.

PROF. WOODBURY will summer at Glen Summit.

PROF. GOODMAN is going to Europe, and will visit Vienna.

A MALE beauty show will be held in Vienna this summer.

PROF. DA COSTA has gone to his summer residence at Villanova.

TWENTY-NINE deaths from starvation were reported in London last year.

PROF. GARRETSON has located his family at Swarthmore for the summer.

PROF. SHOEMAKER is writing a book upon Therapeutics; which will appear during the coming autumn.

COOLNESS, fresh air, and regular feeding cannot too strongly be insisted on in treating summer complaint in children.

IN the canton of Zurich, Switzerland, the insane amount to 1 per cent. of the population. Alcoholism is said to be cause.

THERE were 386 deaths in Philadelphia for the week ending June 10, against 320 for the corresponding week last year.

"THE MAIDEN'S BLUSH" is the delightfully euphemistic title of a preparation, the purpose of which is to produce a delicate bloom on the purchaser's fair cheek.

THE *Hospital Gazette* mentions two cases of blackmailing physicians in London. Female patients are likely sometimes to prove a terror in England as well as here.

LAST summer *Life* raised a fund which sent over 2000 poor children to the country for a fortnight of country air. The same good work is being done this summer.

A LONDON druggist has been fined for dispensing sal volatile which did not come up to the legal standard. There's some good in the effete civilization of Europe after all.

REGINALD FOSTER, of New York, a Yale sophomore, is seriously ill from blood-poisoning, caused by wearing a rubber boot, the lining of which was colored with aniline dyes.

THE Coroner's verdict in the case of Catharine Heustis, who committed suicide by taking arsenic, gives an illustration of the culpable laxity of the laws concerning the sale of poisons.

THE carelessness of some people in the matter of taking medicine is remarkable. To be added to the already long list is the case of a woman who lately swallowed crystallized sulphate of zinc, thinking it was epsom salts. It is never safe to take medicine in the dark without looking at the label.

EFFECT OF THE IMAGINATION.—An exchange remarks that it knows of an eminent doctor who ordered a fevered patient to read Dr. Kane's Arctic explorations, with excellent results.

THE *Times* published a list of a number of eminent physicians of this city who are opposed to prohibition, on the ground that it is "ill-advised, ineffectual, and ill-adapted to the end in view."

NOW READY FOR DELIVERY. — "The Medical Directory of Philadelphia" for 1889. Price, $2.50. P. Blakiston Son & Co., Publishers, 1012 Walnut Street, Philadelphia.

DR. OLIVER WENDELL HOLMES' principal claim to distinction lies in the fact that he has lived in Boston and its immediate vicinity since 1809, and has not yet fallen a victim to acute melancholia.

—*Life.*

SOME mendacious fellow says that at a boarding house kept by an undertaker's wife the boarders always knew when there had been a funeral, by the appearance of cut flowers on the table and ice on the butter.

A PHILADELPHIA doctor purposes giving to the Johnstown fund one-tenth of the fees from his new patients from the time of the disaster to July 1.

If he be a recent graduate, though, the proposition does not mean much.

A WRITER in the *Provincial Med. Jour.* thinks that, as nearly all the alcohol drinking nations are powerful and the abstaining ones weak, it looks much as if alcohol were rather an advantage, considering the people as a whole.

RELATIVE to a case of poisoning from eating mackerel, the N. Y. *Sun* says: "That the gills of a mackerel undergo fermentation, and no part of the head, or near the head, should be eaten after forty-eight hours of the fish being caught."

THE Delaware Medical Society has elected as delegates to the American Medical Association Drs. Bush, Cordiza, Stewart, Chandler, Hamilton, Marshall, Whitely, Pratt, Cooper, Bishop, Richards, Fowler, Hall, Burton, and Ellegood.

MERCIFUL PROVIDENCE.—A Kansas man had a comparatively easy death the other day. He expired just as he entered a railroad eating-house. Five minutes later he might have tackled a railroad sandwich. Providence is merciful.—*Amer. Analyst.*

THE delinquent Almshouse attendants, Joseph Williamson, Joseph Marshall, and Joseph Devlin, charged on five bills of indictment with maltreating insane patients, appeared before Judge Willson, but by mutual consent the case was postponed to June 25.

DR. AGNEW says a healthy woman can kill herself in about a year horseback riding.

Life gives that item, but we don't believe Agnew ever said anything so foolish in his life. Idleness, over-eating, corsets, late hours, improper clothing, confectionery, thin shoes, and many other items each slay hundreds to one who owes her death to riding.

SOMEWHAT APOCRYPHAL.—According to a St. Louis doctor, he treated through a severe illness the wife of a poor laborer, unable to pay in anything but thanks. A year and a half afterwards this same laborer received a legacy of $100, and he at once came to the doctor and forced $50 of it on him.

THE London University Commission has m de its report, in which it recognizes the justice of the demand for degrees for London medical students, and recommends extension of the powers of the present University, making it a teaching university, which shall have the power to confer degrees.

DR. CRESSON has put in a striking manner the effects upon Philadelphia of impure drinking water. In 1888, the deaths from typhoid fever per million of inhabitants were, in New York, 235; in Philadelphia, 766; but in the Kensington district, supplied with Delaware water, 1190. In London the rate in 1887 was 145.

SOME CHEERING WORDS FOR SMOKERS.—Hajek, of Vienna, has declared that smokers are less liable to diphtheria than non-smokers, in the ratio of 1 to 2.8, and Dr. Schiff says that smoking is forbidden in the bacteriological laboratories, because it is known to hinder the development of bacteria in the various culture-media.

SOME members of the St. Louis Medical Society are displeased with parts of the present code of ethics, and think that certain changes would be good. For instance, Dr. Rumbold believes that physicians should have just as good right as others to patent an invention, and considers the rule an obstruction to scientific development.

ON the supposition that association with certain animals is of benefit to consumptives, a large building is constructing in Reinickendorf near Berlin, in which the afflicted may dwell with the kine. Cows are not so bad, though, but any one who has visited the Zoölogica' Gardens will agree with us that we should rather take our chances on cod-liver oil, than live in the monkeys' cage.

JUDGE RICE, of Wilkesbarre, decides that "a physician is not compelled to attend a post mortem examination on a man mortally wounded, but when he does he cannot withhold his knowledge in a judicial investigation. It is a duty which he owes to the public, although there is no compensation attached to it. The remedy, in order to secure compensation, must be brought before the Legislature."

LEFT AGAIN.—At one of our hospitals, the other day, a patient declared that he had swallowed eighteen pellets of atropia, each gr. $\frac{1}{60}$, and absolutely refused to take any antidotes.

After the house physicians, with some outside help, had thrown the man down, bound him, gagged him, injected morphine into one arm and apom rphine into the other, poured tannic acid and sulphate of zinc down his throat, and followed that up by stomach-pumping him for what the apomorphine might have left, they discovered that the man had lied.

THREE HUNDRED AND EIGHTY-FOUR deaths in Philadelphia last week.

AURAL BLINDNESS.—Such a term might be applied to defects in hearing, such that one is able perfectly to hear one kind of sound but not another. Dr. Robert Barclay suggests that tests for hearing as well as for sight should be applied to those holding positions in which those two senses are much used, such as railroad men, sailors, and the like.

THE LAW OF GRAVITY.—A police officer, who had watched the ineffectual efforts of the hospital physicians to extract a marble from a choking child's throat, picked the child up while they were gone for more instruments, shook it by the heels, and out dropped the marble. This reminds us that a surgeon, who charges $10 for taking a tube out after an intubation, told us that if the parents knew enough to pick the child up by the heels and smack it on the most prominent portion of its anatomy, the fee might be saved.

A LARGE FAMILY.—Some weeks ago we mentioned a phenomenally large family which has been reared in Arkansas. While the one herein mentioned does not compare with that in Arkansas, it is still a pretty large family.

Mr. and Mrs. Lower, residing at 620 North Front Street, Philadelphia, have had eleven children, whose descendants comprise the following:

1. George, one child.
2. Joseph, none.
3. Died in infancy.
4. Mary, ten children, six grandchildren.
5. Elizabeth (dead), two children, seven grandchildren.
6. James, eight children, one grandchild.
7. Cornelia, eight children.
8. Hester, seven children.
9. Hannah, six children.
10. John, six children, one grandchild.
11. Emily, twelve children.

In all Mrs. Lower has had eleven children, of whom nine are living; sixty grandchildren, forty-three of whom are alive, and fifteen great-grandchildren; all living at present; making eighty-six descendants, sixty-seven of whom survive.

It will be seen that the youngest daughter has had twelve children, the eldest being now nineteen years of age. While it is the rule that children born so closely together are apt to be weakly it would be difficult to find a sturdier group of lads and lasses than the ten survivors.

Mr. Lower died a few months ago in his eighty-fourth year, but his widow is still alive, in her eighty-fourth; and is in the full possession of her faculties.

This large family has been raised in Philadelphia. There has never been a case of phthisis, defective sight, hearing or speech, or any nervous or mental disease among its members. The only adult who died had an extra-uterine pregnancy. The children succumed to cholera infantum, croup, diphtheria and scarlatina. Finally, not one has ever been arrested, nor given to drink; but all are reputable, industrious, law-abiding citizens.

DR. JAMES ETHELBERT MORGAN, WASHINGTON, D. C.

The death of Dr. James Ethelbert Morgan, which occurred on Sunday morning, June 2, 1889, removes from Washington one of its oldest and most distinguished citizens.

Dr. Morgan was born in St. Mary's County, Md., September 25, 1822, and received his collegiate education from St. John's College, Frederick, Md. In 1843 he graduated in medicine from the Columbia Medical College, D. C. Settling in Washington, he was during the past forty-four years engaged in the active and successful practice of his profession. Coming to the city in the earlier days, he grew up with the place, becoming widely known and gained the highest confidence and esteem of its oldest and best residents, many of whom have been his earnest and devoted friends.

Dr. Morgan was at the time of his demise Emeritus Professor of Materia Medica and Therapeutics in the Medical Department of Georgetown University, having at various times during a period of nearly thirty years filled the Chairs of Physiology, Materia Medica and Therapeutics, or Medical Jurisprudence and Hygiene in this institution. His lectures on medical jurisprudence and hygiene were among the earliest delivered in the United States on these subjects and attracted general attention.

He contributed a number of articles upon medical topics to the literature of the day, among which may be mentioned one on "Paronychia an Epidemic," *American Journal of the Medical Sciences*, Vol. XXII, 144. His "Defence of Medicine and of the Medical Profession," at Washington, 1884, pp. 16, delivered before the Medical Society of the District of Columbia, was a powerful and philosophical plea for the value of drugs in the curing of diseases, concluding with the following language: "I believe all diseases are either curable or susceptible of palliation. Our senses demonstrate the truth of this proposition, our reason confirms it, and our instinct impels us to a practical application of it. I, therefore, gentlemen, in conclusion, reiterate that I have the strongest faith in the science of medicine, and that my confidence in it has increased with age, experience and observation; and further, I believe it should be used without hesitation to the utmost extent of its curative powers."

He had been President of the Medical Association and of the Medical Society of the District of Columbia. He was Consultant in the Columbia Lying-in Hospital and in the Central Dispensary, and for many years was a member of the Judicial Council of the American Medical Association. Dr. Morgan was the last surviving officer of the Convention of 1870 for the decennial revision of the United States Pharmacopœia, and convened and organized the Convention of 1880.

Dr. Morgan, with Dr. Robert King Stone, was appointed to investigate the causes of the celebrated National Hotel disease, an endemic of historical importance, which occurred in 1857, and which will be remembered by our older readers.

In the early days of the city, Dr. Morgan served in the Board of Common Council and the Board of Aldermen, and some thirty years ago was attending physician to the Washington Asylum and Smallpox Hospital when that institution was in its infancy. He had charge during the late war of the large quartermasters hospitals situated in Farragut Square, also of the Soldiers' Retreat, and was surgeon to the militia of the District about 1854. His fondness for teaching medicine attracted many students to him, twenty-two being the number of his office pupils in one year. He was for years a regent of the National University.

An earnest student of colonial history and a finished classical scholar, Dr. Morgan retained his proficiency in and fondness for these studies to the last.

He leaves a widow, the daughter of Dudley Diggs, of Prince George's Co., Md., and six children, three daughters, one of them the wife of Emory Speer, United States Judge for the Southern District of Georgia, and three sons, two of whom, Dr. Ethelbert Carroll Morgan, the well-known laryngologist, and Dr. J. Dudley Morgan are practising physicians in the city of Washington, while Cecil is engaged in business in the South.

Personally, Dr. Morgan was of commanding figure, fine address, and great geniality of disposition, a devoted physician, a courtly gentleman, and a man whose sterling qualities were recognized by all.

THE *Medical Press* says that a hospital at Newcastle-on-Tyne has been run as a house of prostitution by the thrifty care-taker. The discovery was only made when one of the boarders, while drunk, went down to the drug room and helped herself to a fatal dose of strychnine.

A VERY practical philanthropist is Mrs. Schaffner, who visits the New York police courts, and supplies legal advice and bail to prisoners apparently innocent. She has never lost a case or forfeited bail. Tally one more for the unerring instinct of a good woman.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 4, 1889, to June 10, 1889.

MERRILL, JAMES C., Captain and Assistaut-Surgeon. Detailed as a member of the Board of Medical Officers, appointed by Par. 9, S. O. 198, May 10, 1889, from this office, by direction of the Acting Secretary of War, to meet at the United States Military Academy, West Point, New York, on June 1, 1889, or as soon thereaf er as necessary, to examine candidates for admission to the Academy, etc., vice Captain Fred. C. Ainsworth, Assistant-Surgeon, hereby relieved as a member of the Board. Par. S. O. 131, A. G. O., June 3, 1889.

OWEN, W. O., JR., Ca tain and Assistant Surgeon. Leave of absence granted for seven days, in Orders No. 18, C. S., Fort Gibson, Indian Territory, is extended twenty-three days.

KEAN, JEFFERSON R, First Lieutenant and Assistant-Surgeon. Leave of absence granted by direction of the Secretary of War, in S. O., No. 38, May 13, 1889, Department of the Platte, is extended fifteen days. Par. 3, S. O. 129, A. G. O., June 5, 1889.

Appointments in the Medical Department, U. S. Army.

WALES, PHILIP G. Appointed Assistant-Surgeon, with rank of First Lieutenant, from June 7, 1889.

DEWITT, THEODORE F. Appointed Assistant Surgeon, with rank of First Lieutenant, from June 7, 1889.

TEN EYCK, BENJAMIN L. Appointed Assistant-Surgeon, with rank of First Lieutenant from June 7, 1889.

Changes in the Medical Corps of the U. S. Navy for the week ending June 15, 1889.

MORTON, O. D., Assistant-Surgeon. Ordered to the Naval Hospital, Chelsea, Mass.

HALL, J. H., Passed Assistant Surgeon. Detached from the Naval Hospital, Washington, D. C., and granted six months leave to go abroad.

LEWIS, D. O., Passed Assistant-Surgeon. Detached from the Naval Academy and ordered to Hospital, Washington, D. C.

BRIGHT, GEO. A., Surgeon. Detached from the Navy Yard, Norfolk, Va., and wait orders.

MAVMEM, R. A., Surgeon. Detached from the Receiving-ing-ship "Franklin," and ordered to Navy Yard, Norfolk.

BERTOLETTE, D. N., Surgeon. Ordered to the Receceiving-ship "Franklin."

KIDDER, B. H., Medical Inspector. Ordered to the Naval Academy, Annapolis, Md.

WALTON, T. C., Medical Inspector. Detached from the Naval Academy and ordered to the U. S. S. "Chicago."

BEVER, H. G. Passed Assistant-Surgeon. Ordered to the Training-ship "Portsmouth"

Clinical Lecture.

FEEDING OF CHILDREN.

(Delivered at Philadelphia Hospital.)

BY S. S. STRYKER, M.D.

GENTLEMEN: My advice to you is to urge upon mothers the necessity of nursing their own children if they are able; if their nipples are good and their milk nourishing. The child should be put to the breast a few hours after birth, as it empties the milk ducts and obtains that which will be a benefit to it, as well as a relief to the mother. Young children should be nursed every hour or so, and as they grow older the time can be lengthened, and this is the rule to be observed from early morn—5–6 A.M.—until the mother's bed-time.

Do not allow the child to get into the habit of nursing at night. Nurse it and let it go to sleep, for all it is good for now is to eat and sleep. Put it into a bed or crib by itself, and do not toss it about in the arms or cradle, for it is less likely to churn up the stomach, and less likely to cause disturbance of the stomach and gastric canal. Teach it to go to sleep without swinging or rocking. Do not, under any condition, allow the use of sugar-teats or sweetened water, for you will be sure to make it sick. Do not cater to the desire and superstitions of the nurse or old women, as this usually leads to harm.

It is well to prepare the nipple before birth by manipulation and astringent applications. The milk should be coaxed from the periphery to the nipple by gentle friction along the ducts. Teach the child to nurse from both breasts alternately. When the child is six or eight months old, if it is strong and healthy, recognize the fact that it is not well to confine it strictly to the mother's milk. It is an old custom to nurse a child for eighteen months, but I do not adhere to it, as it ought to be nursed off and on for a year. When it is eight months old it should receive some artificial food, and I think it will do better than by giving the mother's milk alone. It is also much better for the mother, as the constant nursing is a drain on her, and you have no business to allow this.

How often had the food better be given? If the mother has a generous supply, nurse once or twice and feed once; if not as generous as it should be, nurse once and next time feed. If it cannot be fed in this way, it is well to have the mother relieved, so feed it at 5–6 P.M., and nurse once during the night, and feed it again in the morning. You are often called on to prescribe food for a child that cannot be nursed by the mother, so the subject of artificial feeding comes up. There are many foods that are recommended but let me say at the outset that it is not well to use them, for milk is the only thing that I would recommend you to use, and nothing else.

You will read in the books and be taught that the milk of the ass or the goat can be made nearer the

mother's milk than any other, but as you cannot readily obtain it in all cases, you will often be compelled to use cow's milk. I think cow's milk is as good as the milk of the ass or the goat, when properly prepared. The milk of the cow is heavier and denser than the mother's milk, and must be diluted by a certain amount of pure water, and thus take the first step in its preparation. Take good, healthy cow's milk and dilute with three parts of pure water, and you have the right proportion. Add a small amount of sugar of milk and one-half teaspoonful of lime-water to the ounce of milk. At first a child will take one ounce of milk at a feeding, but as it grows older you must be governed by its needs, and never overfeed, as it will cause vomiting and other troubles. As it grows older you may add a tablespoonful of cream to 6–8 ounces of milk, but in the case of the newborn this is unnecessary. Never give milk cold, but heat to the temperature of the body in a water-bath to avoid scorching. Make the food fresh every time it is used. Milk is a very treacherous sort of thing, and unless you have opportunity to get it fresh twice in twenty-four hours, it will be necessary to put it through a process of sterilization to keep it from fermenting. During the summer season it is always well to scald or boil it for fifteen minutes before placing it in the ice for preservation. Where milk must be prepared for a number of children, we resort to the use of a sterilizer for the destruction of germs and the preservation of the milk.

I would call your attention to this form of sterilizer which for neatness, compactness, and cleanliness is an improvement on the others already shown to you. The bottles are rounded and graduated, and can be cleansed readily as they have no corners. Each bottle is provided with a perforated rubber cork into which fits a solid glass rod. Cleanse the bottles and corks in hot water and fill with the prepared milk. Place them in this wire basket, and then the whole into this large receiver of tin. Cover the bottles almost to their mouth; cover the receiver and place the whole over an alcohol lamp or stove and boil fifteen minutes. Remove the cover and adjust the rubber corks and boil fifteen minutes longer; when the glass rods are to be put in the corks tightly and the bottles placed on the ice ready for use.

When the child is seven or eight months old it is time to give it something else than ordinary milk; then come in the various preparations of infant foods. It is not my purpose to advertise or use any one particular food, but when used you can incorporate it into the milk and begin with ʒi–ʒvi of prepared food, according to the age and strength of the child.

When one year old, in the middle of the day, give it some thin broth with cracker crumbs or bread, and it will relish this and be more healthy. You may give raw or soft-boiled egg, or defibrinated, scraped raw meat. Where digestion is weak, peptonizing the milk is now common, but must not be carried too far, as the milk will taste disagreeable. Where milk is peptonized do not heat longer than twenty minutes, and never prepare more than too feedings at one time, as it undergoes certain changes very readily. A child with a feeble digestion can then digest the milk that has been partly pre-digested and will grow and nourish on it. The great object in the administration of cow's milk is to avoid the formation of hard curds, and peptonizing obviates this. The curd from the mother's milk is light and fluffy and easily digested. One of the best substitutes for cow's milk is the well-known condensed milk. It is easily prepared each time it is used and keeps in all climates and temperatures. I would advise you never to use it stronger than one part of the condensed milk to twelve of water. It has the objection of being too sweet, but in summer time, when milk cannot be obtained fresh, it is invaluable as a substitute.

Original Articles.

THE CURE OF CROOKED AND OTHERWISE DEFORMED NOSES.

(Read June 12, 1889.)

By JOHN B. ROBERTS, A.M., M.D.,
Professor of Anatomy and Surgery in the Philadelphia Polyclinic, Lecturer on Anatomy in the University of Pennsylvania, Surgeon to St. Agnes' Hospital.

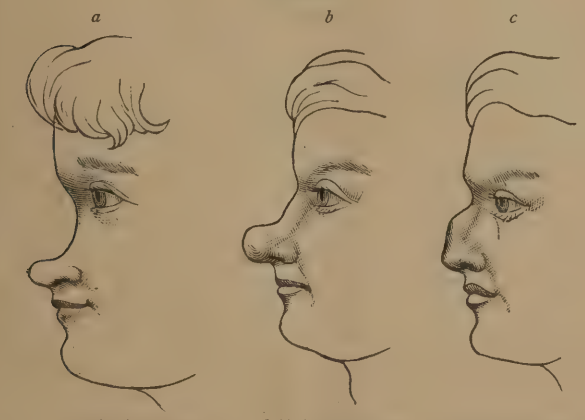
THERE are many instances of nasal deformity which are a great trial to those who have to bear the disfigurement through life, and whose correction would add much to the popular appreciation of surgery and at the same time be a source of revenue to the operator whose skill succeeded in relieving the unsightly condition. Many of these defects are mere blemishes upon the face of the subject, rather than matters of very great importance. There may be little or no obstruction to breathing, and very little deformity to the eye of the observer, but the disfigurement causes such a mental effect on the patient as may even lead to a change in the disposition of the person. If we can relieve these minor disfigurements, and thereby relieve the worry and anxiety of the patient, we do something which is entirely justifiable.

Many forms of defect are found in the physical contour of the nose, and many are the causes giving rise to the varying types of nasal distortion. Faults of development are not uncommon. Accidental injuries, causing fracture or dislocation of the bones or cartilages, many occur in infancy, or at any time of life, and leave thereafter a very much disfigured organ. Blows of an opponent's fist, falls from a horse or carriage, and injuries received while playing ball, are not infrequently the disfiguring traumatism. We may also have deformity due to wounds made by cutting instruments, whereby portions of the soft structures have been lost, or to unseemly cicatrization after such wounds. Syphilis, giving rise to necrosis and ulceration of the bones and cartilages, thereby allowing the bridge of the nose to fall in or other changes to take place, is a potent cause of nasal deformity. Ulceration of the alæ of the nose due to syphilis, while in the early stage necessitating active treatment, may later require surgical operation to reconstruct the lost part. Again, in epithelioma it may be necessary to cut away the ala and at once make a new structure. It may, at other times, be necessary

to make a new tip to the nose after such an excision for malignant disease. By looking at a skull it is seen that if the septum and nasal bones are destroyed by syphilis, there is a great tendency for the bony arch, or bridge, to sink in and allow the tip or the nose to turn up; thus leaving only the small prominence formed by the wings and lobe of the nose, and causing great disfigurement of the front part of the face. Again, you may have lateral openings in the nose following specific ulceration. I have under observation at the present time a patient with an opening due to syphilitic ulceration, who has not yet agreed to an operation, but who will possibly do so in time.

I have drawn here a number of badly shaped noses, which can be remedied by operation. We may have a nose which sinks in at the top, in which there is

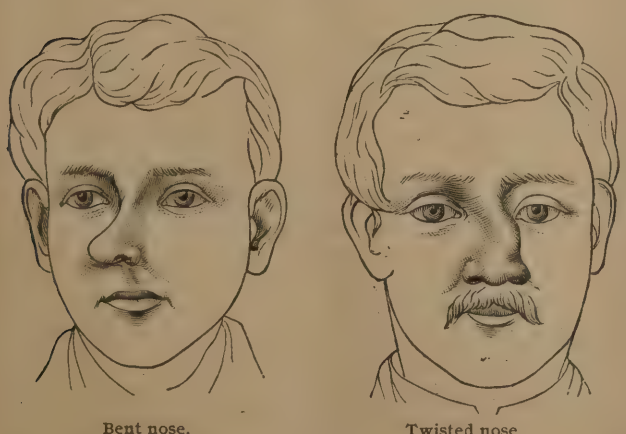
FIG. 1.



a Saddle-back nose. *b* Tuberous nose. *c* Angular nose.

not much bridge. This is generally due to want of proper developement of the bones and cartilages forming the septum, and is sometimes called the saddle-back nose (Fig 1, *a*). A similar nose is often found in inherited syphilis. Then we may meet with a nose bent a good deal to one side (Fig. 2). A slight degree of this deformity is very common. Again, the organ may be not simply bent, but bent twice or irregularly, twisted, as is shown in this drawing (Fig. 3). Bent and twisted noses are very often due to fractures received in early childhood. It is not un-

FIG. 2.



Bent nose. Twisted nose

usual to see a nose with a large lump on the end of it, which may be due to hypertrophy of the lobe or to a new growth developed there. This disfiguring condition is frequently due to acne rosacea, causing unusual development of tissue. This I call the tuberous nose (Fig. 1, *b*). I often see a man who has exceeding hypertrophy of the tip of his nose from acne rosacea, and whose son curiously has a similar nose, but not quite so greatly developed. Both these men could be greatly improved by operation. The last variety of which I shall here speak is what I call the angular nose (Fig. 1, *c*), because of the angular appearance of its dorsum, due to an unnatural bony prominence at the lower margin of the nasal bones. A lady came into my office a short time ago with such an elevation on the middle of the nose, due to a bony mass resulting from a fracture in infancy. There is also some stopping-up of the nostril from the fracture, and the occlusion has so interfered with respiration that she has been a mouth-breather since she was three years old. As a result of this the lower jaw has not developed, and she cannot bring the incisor teeth together. She is much more concerned, however, about the appearance of her nose than about the obstruction to breathing. This patient, as well as those suffering from the other varieties of nasal deformity, can be greatly improved in appearance by proper and judicious surgical interference.

These illustrations, several of which are taken from a paper by Dr. S. B. Parsons, give an idea of the ordinary deformities which we have in the contour of the dorsum or bridge of the nose. A good many deformities also occur in the septum. In some of the cases just referred to there is not necessarily much deformity in the septum. In twisted and bent noses, however, there is usually some septal distortion, because the condition, as a rule, is the result of injury.

The peculiar broad and flattened appearance of the root of the nose seen in epicanthus, may be included in this enumeration of nasal deformities. Such cases are more apt, however, to be seen by those of us who practise ophthalmic surgery, than by general surgeons who do not attempt eye-surgery. The condition is remediable by dissecting an elliptical portion of skin, with its long diameter vertical, from the root of the nose and bringing the edges together with sutures. It is well in cases not very marked to delay operation, however, until the child has grown up, because the development of the bony structures of the nose may cause a spontaneous cure of the deformity.

In cases of crooked nose from traumatism, it is very common to have a greatly deformed septum. It is difficult, in fact, for a fracturing injury to cause much permanent nasal deformity without the cartilaginous or bony septum suffering some lesion at the time of the traumatism. The vomer and the perpendicular plate of the ethmoid are thin and easily broken, while the triangular cartilage is also readily fractured; hence, in nearly all deformed noses due to blows, deformity of the septum is found. The septal deviation usually interferes with respiration, because one nostril is more or less occluded. This causes change in the tone of voice and induces other well-known symptoms.

Some persons are more annoyed by the nasal obstruction than by the want of physical comeliness in

the external organ. Others care little about the patency of the nostrils, but worry greatly about the unsightly appearance of the deformed nose. Thus it is that patients come for the relief of one or the other condition, according to the character of their dispositions.

Congenital deviation of the septum is by no means infrequent, and may in a similar manner interfere with proper respiratory performance. Such deviation of the septum is more apt to give rise to a curved bulging on one side than to an angular projection. Deviation of the septum due to injury is apt to be angular, and is very often accompanied by cartilaginous or bony outgrowths about the original lines of fracture. If the fracture has comminuted the septal structures to any great extent, both nostrils may become entirely filled with a mass of bone and cartilage. I once saw a case in which nostrils had to be made by actually quarrying through a mass of this kind by means of a chisel.

FIG. 4.

Normal. Curved. Angular. Enchondroma. Bridge of cartilage. Sigmoid.

Diagrams showing usual variations in shape of septum, as seen when observer looks into anterior nares.

In these and other deformities small enchondromas may be found near the attachment of the septum to the floor of the nares, and in any form of septal distortion bridges of cartilage and bone may extend across the nasal chamber from the septum to the turbinated bone. These bridges at times are apparently formed by the coalescence of two opposing masses, just as a column is made in a cavern by the union of a stalactite with an opposing stalagmite. Cartilage tumors in the nose will often be found to have bony nuclei. This fact is worth remembering when the surgeon expects to attempt removal by a single incision made with a knife. Occasionally the septum has a double or sigmoid curve from above downward, as is shown in the last diagram on the blackboard. At other times the double curve is antero-posterior, so that one nostril is occluded in front and the other nostril occluded in the back of the nasal chamber. When one nostril is obstructed by what appears to be a deviated septum, it may happen that careful examination discloses the fact that there is no corresponding abnormal patency of the other nostril. The condition then is one of abnormal thickness of the septum, with a great degree of overgrowth on one side. This is to be treated by paring away the excess of cartilage or grinding away the redundant bone with the burr of the surgical engine.

In septal deviation the distortion is, fortunately, nearly always in the anterior two-thirds of the septum. Hence the deformity is more accessible to operative attack than would be the case if the converse were the rule.

There are many methods of relieving these nasal deformities. The method adopted must depend on the character of the condition. If the bridge is sunken, it must be raised and supported by the intranasal tissues. If the nasal bones are destroyed by syphilis, they must be substituted by new tissue, which is usually the tissue of the cheek or forehead, with possibly periosteal or osseous structures taken from the frontal region or from a lower animal. If there is a protuberance at the tip of the nose, it must be cut out and the two sides brought together so as to form a respectable-looking lobe. If the septum is bent over, it is necessary to open the occluded nostril, straighten the septum and keep it in the median line.

It is especially important that all recent fractures of the nose should be skilfully treated at once, in order to avoid subsequent deformity. This often is not done. There is a good deal of swelling and pain at the time of injury, which makes it difficult to determine the extent of the lesion; and as the condition is not serious, very little attention is given it, the structures are not accurately replaced, and in a few days, when the swelling subsides, the bones and cartilages are found to have united in bad positions. As a result, one of these deformed noses is the patient's burden through life, subjecting him to the criticism of his friends and the jeers of his enemies. Sometimes the displaced portion of bone is so sharp that it almost projects through the skin.

When a fracture occurs, diligent and intelligent efforts should at once be made to restore the bones to their proper position. Anæsthesia should be resorted to if necessary, rather than have the replacement not absolutely correct. By looking at this specimen you see that the space under the nasal bones is not very great. In many text-books the surgeon is directed, in fractures of the nasal bones, to insert the end of a female catheter into the nostril, to push the bones into place, and then to put a plug or pad of lint in the nostril. Since the normal space under the nasal arch is narrow, and since in fracture there is great swelling of the mucous membrane, it is practically impossible to follow these directions, because the catheter is too wide. One can, however, get a thin instrument, like a steel director or the back of a small nasal saw, up under the bones. With this they can be elevated into place, and the bridge of the nose then moulded into proper shape with the fingers on the outside of the injured organ. These fractures heal with great rapidity, hence anything that is done must be done promptly, as in four or five days the union will be so firm that it will be almost impossible to restore the bones to their proper position, if the fragments have been left in a condition of deformity.

Syphilis of the nose is exceedingly liable to cause destruction of the bony and cartilaginous nasal structures, and, therefore, should be treated immediately on its recognition with *large* doses of mercury and potassium iodide. Many cases are, however, unrecognized or are insufficiently treated, and as a result we have unsightly and unnecessary deformity. Superficial scars can sometimes be relieved by scraping away the irregularly cicatrized surface, since the irregularity in the cicatrization often looks worse than a large, smooth scar would. A greater degree of

damage will require for its repair the best efforts of a skilled plastic surgeon.

Just here let me say that in operating upon the skin of the nose or face an incision made obliquely through the cutaneous tissue leaves a very faint cicatrix, because more correct apposition is obtained when the sutures are inserted. This is illustrated by cutting a card first obliquely and then perpendicularly to its surface. You see that when the pieces are brought together the line of union made at the former incision is not so distinct as that made at the latter place. A good deal of scarring may, however, be made about the nose and yet not show very much finally, if the parts are brought accurately together, and the union takes place rapidly. This is especially true in the rough and coarse skin of many persons, where lines and creases about the nose are normally present.

There are some special plans of treatment which are valuable, and to which I shall now refer. When, after fracture of the nose and adjustment of the fragments, there is a tendency for them to become displaced again, they can usually be kept in position by what is known as Mason's method, though it is really a revival of an old method. With an ordinary awl or small drill bore a hole transversely through the bones, and through this thrust a steel pin, to the projecting ends of which attach the ends of a rubber band, so placed as to pass across the bridge of the nose. This band should be so tightly stretched over the nose as to hold the bones up in position. The pin thus acts like the tie-beam which holds an arch together. The tendency of the rubber is to draw the pin up and thus it supports the arch. I thought that I had something new when on this same principle I put a pin through the nose and clamped a shot on the end; but I found that a similar thing had been used many years ago. When the surgeon does not wish to use the rubber band, he can clamp shot on the end of the pin, and have the upper part of the nose constantly under observation. Filling the nostrils with plugs of lint or other material to hold the parts in correct position is usually an ineffectual and uncomfortable method.

These methods may be employed in the treatment of recent fractures, or in cases where it is desirable to make a fracture in odor to overcome deformity.

In correcting osseous deformity of the nose, whether congenital or due to fractures received many years previously, it is very easy with a proper chisel or saw to divide the bones to any extent and in any direction. For most of these operations the ordinary cold-chisel previously ground to a fine, sharp edge, answers very well. These chisels can be bought for a few cents at the hardware stores. To loosen the nasal arch a small opening should be made at the side of the nose, at the junction of the nasal bone with the lateral cartilage, and the chisel then driven up between the nasal bone and the nasal process of the maxillary bone nearly as high, or quite as high, as the supra-orbital ridge. The same thing should be done on the other side. The naso-frontal junction can be separated by introducing a strong steel instrument into the nose and elevating the nasal bones until fracture occurs near or at the suture line, or the bones can be cut loose by introducing a small chisel at the top of the nose. If it is considered necessary, small perforations with a drill may be made along the junction of the frontal and nasal bones before fracture there is attempted. The bones can then be placed in any position desired and held there by a pin, thrust through the nose below them or made to perforate them after drilling with an awl. The circulation of the parts is so good that necrosis is almost impossible. The scars formed by the openings made for the introduction of the chisel cause much less deformity than that for which operation is performed. The nasal bones unite in four or five days without provisional callus, and if they are placed in good position a comely nose results. In some cases it may be better to introduce a small, narrow saw into the nostril and saw the bone off on both sides. The chisel is rather a cruder way and perhaps not so accurate.

When the bridge of a nose is sunken in a good deal, when it is in fact a little like the saddle-back nose, a gutta-percha splint adjusted to the dorsum of the nose may be used to advantage, after a tenotome, introduced into the nostrils, has been used to cut all structures loose. The gutta-percha is placed in hot water until soft, and then moulded to the nose and allowed to cool, thus forming an external nasal splint. After loosening the bones and soft tissues, the operator carries a wire or silk suture through the nose below the splint and brings the ends up over the splint and ties them. This lifts the middle line or dorsum of the nose into the proper position. After a few days cicatrization takes place and the normal conformation of the noise is maintained. I have not tried this method, but it seems as though it were a good one.

Another method of keeping the nose in place, is to put plugs of lint, oakum, wood, glass, gutta-percha, or silver, either solid or hollow, in the nostrils. They may be held in place by straps across the nostrils or by passing a pin through. If the plugs are tubular they soon become clogged, and should be removed every day or two to be cleansed.

If there is an unseemly bony angle on the bridge of the nose, as in Fig. 1, *c*, it is proper to make a straight incision down the middle line of the nose, turn the skin aside, chisel off the mass, and then bring the skin together. There would be a red cicatrix for a short time, but it would soon lose its color and become a white line, which would be scarcely noticeable.

When we come to the treatment of deviations of the septum we have to use different devices to meet different indications. Clamps have sometimes been applied so as to make pressure upon opposite sides of the septum. The clamp is left in position for several days, until the septum has become fixed in its new position. If the septum is bent to one side and the surgeon attempts to alter it by forcing it over and holding it in position by plugs, the patient will have to wear the plugs for weeks. Such patients may occasionally be seen going about the streets, and are noticeable because the string fastened to the plug is attached to the cheek by plaster. I do not believe that these simple measures will effect a cure except

when the deviation is very slight. I have forced the septum over by the dilatation of a laminaria uterine tent put in the nostril, but the result was very temporary. As soon as the plug is removed, there is a tendency for the resilient septum to resume its original position.

There are several other ways of overcoming septal deformity and the consequent nasal occlusion. One of the old methods is to cut out a piece of the septum at the point of deviation, if the deviation pertains to a limited area, so that breathing can go on through either nostril. An objection to this method is that sometimes there occurs necrosis of the cartilage along the edge of the opening. At other times there is a constant tendency to the deposition of crusts thereon. I, however, do not think that the method is as objectionable as some have thought it. The operation is

FIG. 5.

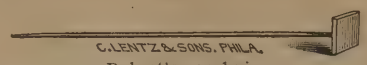
Roberts' nasal punch.

best done by the nasal-punch shown in the figure, which is a modification of that of Blandin's, and acts better than his device, because it divides the mucous membrane on both sides of the septum more readily and perfectly.

Here is a pair of forceps, variously known as Steele's or Sajous' forceps, which cuts a stellate incision in the septum. By this means the septum is weakened, and can be pushed into place. If the deviation is very great, you may have to cut the septum in many places with these stellate forceps, and make it quite flexible. It then becomes almost as soft as wet cardboard, and can be pushed into position and be kept there by plugs or pins until cicatrization takes place.

The method of which I am most fond is to make a long incision at the most prominent portion of the deviation, and supplement this by chopping the septum full of incisions with the stellate punch. If some small triangular pieces are removed by the interlacing of the incisions made with the forceps, it makes no difference, since the openings left are very small and will soon become closed. If there is an angular deviation close to the palatal process of the superior maxillary bone, I make an incision from front to back at the most prominent part, and do not chop the upper portion with the stellate punch. If the deviation is a curved one, I split the cartilage along the most prominent portion and then chop the rest of the septum until it has lost its resiliency. Afterward I cut away with the chisel or saw any horizontal bony edge that may remain at the bottom. To hold the septum in place I usually use steel pins, either those with spherical heads of glass or the flat-headed pins which I devised some years ago. When the head of the pin is to be within the nostril, those with the glass heads are better; when the head is to lie flat against the exterior of the nose, the flat heads are preferable.

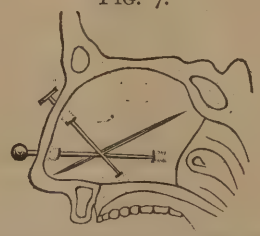
FIG. 6.



Robert's nasal pin.

This method, which I employ so frequently to hold the septum in position, is a device of my own, and is difficult to render clear by a mere description. After having divided the septum, with a knife, along the most prominent part of the deviation, and having made the cartilage flexible by multiple incision with the stellate punch, I introduce a pin into the more open nostril and thrust its point through the anterior part of that portion of the septum which I wish to control and keep in a new relation to the other portions. After I have displaced this part into the desired position, I thrust the point of the pin onward and bury its point deep in the tissues at the back part of the nasal chamber which was formally occluded. This holds the septum firmly in its new position. The head of this pin will be just inside of the anterior naris which was not obstructed, and will lie against

FIG. 7.



Robert's method of holding septum in correct position by means of pins. The upper part of the septum, immediately above the oblique incision, projected too far this way (*i. e.*, toward the reader). It is now pressed the other way (*i. e.*, from the reader), and is held there by the pins.

the columella. It should be allowed to remain about one week, for if left a longer time its head will probably cause ulceration of the columella, and may become deeply buried in the tissues of the columella. Its work is usually accomplished within a week. It is often well to introduce a second pin from the external surface of the front of the nose just below the nasal bones, which aids in keeping the septal cartilage pinned into proper place. If this pin has a flat head, it may be covered with a small square court-plaster. The patient can then go about the streets without attracting attention.

By this method there is no plug to obstruct the nostril, and the patient can snuff up any cleansing wash desired. It is the neatest and most satisfactory way of rectifying deviated septa which has ever been employed by me, or with which I am acquainted. Its employment for four or five years has given me increased confidence in its value, both in cases of simple deviation of the septum and in cases where more complicated operations have been simultaneously required to correct nasal distortion.

Some operators correct crooked septa and other deviations of the nose by seizing the septum between the two blades of an Adams' forceps, and fracturing the intra-nasal structures sufficiently to allow of their reposition in conformity with the natural outlines. A head-band with pads and screws, a mask with adjustable pads to produce pressure on various portions of the nose, or an intra-nasal truss or clamp, is then called into requisition to maintain the position

so obtained. This mode of operating seems to me less accurate, less scientific, and much more annoying to the patient than my method by incision and pins.

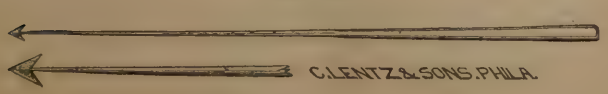
It is said that in some instances of deviated septum, the middle turbinated bone in the non occluded nasal cavity is greatly hypertrophied, and may, by reason of its bulk, interfere with the surgeon's efforts to push the septum into the median line. If such interference exists, the turbinated bone should be partially or entirely excised, in order that reposition of the septum may be effected.

In operations which are not very severe, local anæsthesia is readily obtained by placing a pledget of cotton, moistened with a four per cent. solution of cocaine, in the nostril and allowing it to remain for a few minutes. In operations which are prolonged, it is better to give ether. The disadvantages of anæsthesia are that the blood runs into the throat and the patient vomits; but, on the other hand, the surgeon is more apt to do a thorough and satisfactory operation if he has an anæsthetized person with which to deal. I do not like to plug the posterior nostrils, because the string coming out through the anterior nares may be cut during the operation and the plugs be thus allowed to fall into the pharynx. Occasional cleaning of the fauces, by turning the patient on his face, is all that is required when no plugs are used.

In order to get rid of horizontal ridges of bone and cartilaginous growths that may be present in either nostril, I use one of these small saws, or a chisel and mallet. If the growth is entirely cartilaginous, it may be removed with a bistoury or with this sickle-shaped cartilage knife, which is placed behind the growth and drawn forward.

The enchondromatous tumors found growing from the septum often have a bony center, and the surgeon may find it difficult to remove it with the ordinary knife, and be obliged to use a chisel or a saw. There is a little knack required in removing these cartilaginous masses neatly. If you undertake to use a knife, or a knife and saw, in the ordinary way, you readily cut through the mucous membrane on the upper surface of the tumor, and the tumor itself, but when you come to the mucous membrane underneath, which is very loose and flaccid, it does not offer sufficient resistance to be divided quickly and neatly. The tumor is perfectly detached above, but is attached below by a band of mucous membrane which is difficult to divide, because you cannot see where to apply the forceps or scissors on account of the blood in the nostril. To avoid this annoyance, it is best to cut through the mucous membrane below the tumor first, and afterward to cut down from above with the saw, chisel or knife, when the tumor at once falls out. Another device that is very satisfactory is, first to transfix the tumor with a barbed needle, which acts as a handle by which to hold the tumor steady while excising it.

FIG. 8.



Robert's barbed needle.

Of course, this is not available if the enchondroma has much bone in its interior.

Dr. Seiler has suggested that a grooved director be slipped under the cartilaginous ridge or tumor, with its groove presenting toward the mass to be removed, and that a triangular or ploughshare-shaped knife be then pushed along the groove so as to cut off the excrescence. He also employs for removing such growths chisels and gouges of varying shapes set at an angle in a detachable handle. These devices facilitate at times the neatness and rapidity of the operation.

The means to be employed in correcting the deformity in cases of bent and twisted nose vary with the characteristics of each case. Indeed, it often happens that the nasal distortion combines the peculiarities of more than one type of deformity. I recently saw a gentleman, for example, whose badly bent nose, due to injury sustained in a runaway accident, was made additionally ugly by a large and unshapely lobe or tip. It is necessary, as a rule, in remedying bent or twisted noses, to cut the cutaneous structures thoroughly loose from the septum and nasal arch by free subcutaneous incisions. This is done with a tenotome introduced usually, but not always, through the nostril, and then carried under the skin. I prefer this method, in order to make as few punctures on the cutaneous aspect of the nose as possible; though, as before stated, small incisions or punctures leave in the end very little scarring. After the external nose has been thus loosened by subcutaneous "undermining" with the tenotome, it is necessary to get rid of bony projections by means of the chisel, to cut away any bone or cartilage occluding the nostril, to divide and readjust the distorted septum which is usually present, and then to seize the nose with the fingers and twist or bend it into its normal position. When the desired position has been obtained the parts must be fixed there by pins or other means until union has occured. This requires about a week's time.

The errors likely to be permitted are insufficient division of the distorted structures, and the application of too little force when the attempt is being made to press the organ back into its normal relation with the face. If the surgeon will recollect what a great degree of force is required to produce the distortion found in accidental nasal deformity, he will better appreciate how much force he may use with impunity in endeavoring to correct these and similar disfigurements.

The tuberous nose and the angular nose are easily improved by simply cutting away the excess of tissue and uniting the resulting wound with fine sutures of catgut or silk. In these, as in all plastic operations, the ingenuity of the surgeon must be exercised to give the least scarring and the most perfect contour. The same shaped nose should not be repared in exactly the same way in every sort of face. The peculiar facial lines of the individual or the shape of his other features has a good deal to do with determining the variety of operative procedure best adapted to the requirements. The question involves not only manual dexterity on the part of the operator, but a con-

siderable degree of artistic training. This is equally true when portions of the nose have to be constructed from the cheeks, lip, or finger-tip. Such rhinoplastic operations, however, are rather beyond the scope of the present paper.

There is only one thing more of which to speak. It is the correction of those great deformities which occur from sinking of the whole upper portion of the nose as the result of syphilis. A woman came to my office a short time ago who was in the habit of wearing continually a thick black veil to hide a deformity due to such a loss of the cartilaginous nasal bridge. The point of the nose was turned up and there was a deep groove over the area of the sunken nasal bridge. What is required in these cases is the construction of a new bridge. This is difficult when there are no remains of the original bony structures. I accomplished it pretty well here, however, as the nasal bones remained. I first made a transverse incision across the nose in the deep groove at the line of junctiou of the deformed organ and the face, cutting thereby directly into the nasal chambers, and then pared everything loose inside. The nose was then only attached to the face by the columna and the alæ, and could be pulled downward and forward so as to give its tip a natural

FIG. 9.

Diagram of original deformity.

FIG. 10.

Diagram of flap.

FIG. 11.

Diagram of sutures.

prominence or elevation beyond the cheeks. This procedure left a large opening between the lower portion of the nose and the nasal arch and frontal bone, through which I could look directly into the nasal chambers; and which had to be covered with a flap. I laid over it a triangular flap of skin and superficial fascia, dissected from the space between the eyes and from the forehead. This was slipped downward and sutured in position. The raw surface left on the forehead and at the root of the nose was drawn together as much as possible by sutures, or allowed to heal by granulation. I thought it better to make a triangular incision on the forehead and slip this flap down to cover the opening below, than to turn in cheek flaps. The latter method would have caused more scarring. The soft parts so transplanted were held in place by sutures, and somewhat elevated like a normal nasal bridge by pins thrust across the nose from side to side, upon the points of which perforated shot were threaded and clamped. Pieces of rubber drainage-tube were thrust through the nostrils and upwards under the new bridge, to give greater support. These were not introduced to facilitate respiration, as I intended the patient to breathe entirely through her mouth. When the wound had healed the patient had a nose which was of a pretty good shape, but it was somewhat flabby in the region of the bridge. This is overcome by wearing a pair of spectacles which have little pads on each side of the nose like eyeglasses. These pads pinch up the soft bridge and give it a more natural appearance. This patient has a much better nose than before, although it is, of course, not as good as a normal nose. The other day she came into my office wearing a thin veil instead of the thick black one she had been accustomed to wear. This proved to me that she considered the deformity to have been greatly overcome.

Another way of relieving this sort of deformity is to take a large oval flap from the forehead and turn it down with the skin surface toward the interior of the nose. A flap can then be taken from each cheek and slipped over the corresponding half of this everted or turned-down frontal flap. These super-imposed flaps make a thick mass which simulates the nasal bridge.

Portions of periosteum and thin plates of bone may perhaps be chiseled from the forehead or superciliary ridges and successfully turned into the gap to give solidity to such newly constructed bridges; but I do not know how successfully such operations have terminated, if, indeed, they have ever been actually undertaken. Bone-grafts from lower animals may prove valuable. If there is absence of the ala as the result of ulceration or the removal of tumor, the surgeon should turn in a portion of the cheek or lip. In these plastic operations he can often bring together

FIG. 12.

Diagram of method of making ala of nose from upper lip (Levis).

the edges of the wound left by the transfer of tissue, so as to leave a mere linear scar. Under-cutting the skin before putting in the sutures permits the elastic skin to be drawn over the gap.

If the columella is gone, a portion of the upper lip, including its entire thickness, can be taken out of the centre of the lip and turned up to make a columna. It is then necessary to bring the divided upper lip together as in hare-lip. This manœuvre lessens the size of the lip, but that is rather an advantage, since in such nasal cases the lip usually appears to be relatively too large.

FIG. 13.

Appearance of patient after flap has become adherent in new site, but before the superabundant tissue has been removed (Levis).

You can see from what I have said that many persons having great deformity of the nose can be much relieved if you study the artistic bearings of the case. It is often only necessary to diminish what is too big in order to restore the proper relationship of the parts. If the bridge of the nose is too small, the surgeon can often give the nose a symmetrical appearance by getting rid of a portion of the tip which is relatively, though perhaps not actually, too large. When there is a disparity between the nose and the lips or chin, he may be able to alter the size of the tip of the nose, if he cannot change the other features. The operation which leaves the least scar and brings the parts in the best mutual relation, as to size and appearance, is that which should always be selected.

I have endeavored to show in this address the erroneous character of the teaching which advocates letting deformed noses alone, and which recommends surgeons to advise their patients to bear the affliction of an ugly nose with becoming grace and humility. In this, as in all surgical proceedings, the patient has a right to expect every effort consistent with safety to be made by the surgeon. Procedures such as I have described are practically devoid of danger, are efficient in relieving the mental and physical distress of the patient, and should be done when the patient is willing to assume the moderate temporary inconvenience coincident with the operation.

AT Elmira, a few days since, a man died whose weight was 640 pounds. For some time he gained flesh at the rate of five pounds a week.

AUTO-INFECTION—ILLUSTRATIVE CASES.

BY JOHN J. BERRY, M.D.,
PORTSMOUTH, N. H.

FROM the considerable number of cases observed, I select the following recent ones as being fair examples of this condition. Notes such as these would be unworthy the space accorded them did they not call our attention to the peculiar yet common phenomena of self-poisoning, and at the same time form a text for further comment.

CASE I.—An instance of fibroid phthisis of several years' standing, with daily febrile exacerbations reaching 102°. Night-sweats and attendant phenomena. General derangement of digestive organs, with all the symptoms of the same. Constipation; urine scanty and high-colored; sallow skin, and yellow conjunctiva. There are no physical signs of breaking down of the lung tissue. Under evacuant medication with administration of salol in small doses, and hyposulphite of soda, the evening rise of temperature was diminished to 99⅕° and 100°, while the night-sweats were also lessened markedly in degree. Under this kind of treatment the patient's condition is in every other way improved, but relapses occur whenever it is discontinued.

While some might attribute the results here attained to other causes, it seems clear to my mind that the high temperature was produced, as it generally is, by septic products retained within the system, and that the reduction of temperature was due to their removal by eliminative and antiseptic measures. Auto-infection is one of the pronounced features of phthisis. As soon as the lung becomes crippled and the process of oxidation impaired, the products of tissue waste begin to accumulate within the system, for they are not in such a shape as to permit of elimination. Self-poisoning thus occurs, both from the source above indicated and from the ptomaines of faulty digestion, which must necessarily coexist. It is not difficult to distinguish these symptoms of toxæmia, which occur in early and late phthisis, as well as in many other diseases. They are more or less constant, and their nature may be readily demonstrated by the course of treatment employed. It is not always possible to carry out the method in question without still further impairing the general condition of the patient. While removing the débris of tissue changes, we cannot at the same time stay that destructive process which is constantly in action, much less do anything to repair its ravages; yet many times have I noted a decided improvement in the condition of the consumptive patient under the use of eliminatives and antiseptics, and after I had succeeded in stimulating the glands of the gastro-intestinal tract and increasing the supply of oxygen to the tissues. Certain it is that there is no substance possessing more decided antiseptic and indirectly eliminative properties than oxygen. Without this important adjuvant iron and similar tonics fail, in my experience, to accomplish the work expected of them.

CASE II.—A man of middle age had been suffering for a week or more from malaise, headache, insomnia, anorexia, and at times nausea, feelings of "feverish-

ness," neuralgic pains, and latterly sore throat. Temperature 99°; pulse 70. Urine loaded with phosphates; no physical signs whatever to indicate organic disease, or even functional trouble of any particular organ. This case received several consecutive doses of blue mass and Rochelle salts, followed by muriate of ammonia, in fifteen-grain doses, three times daily. Relief was prompt and permanent.

Cases similar to the above are, I presume, of occasional occurrence in the practice of every physician. They have been often included under the comprehensive, but faulty, term of "billiousness," yet there is no reason for presuming that the liver is the sole organ at fault. As the result of suppressed or deranged secretion of all the glands of the alimentary canal, brought about either by improper food, deficient exudation, or other causes, there are turned back into the general circulation the imperfectly converted, and, hence, toxic products of tissue repair. The contents of the digestive tract, in the absence of the various antiseptic secretions, undergo fermentation, in one form or another, thereby generating many and varied poisons.

It has been shown that it is not the germ itself which is so dangerous, but the products of decomposition which it engenders. To such sources, I think, may be attributed, not only these functional disorders, but the various catarrhal conditions of the mucous membrane. The results of treatment seem to confirm such a theory. The simple evacuation of the gastro-intestinal tract by non-irritant drugs, together with the necessary diet and hygienic rules, are often in themselves sufficient to effect a cure of such disorders. I am becoming every year more firmly convinced of the great efficacy of elimination, and the thorough and persistent oxidation of the various tissues of the body, in the treatment of chronic catarrhal affections of whatever nature.

To secure the best results, the tissues should be flushed, as it were, not only with water, but with oxygen as well.

Case III.—A child, six years of age, came under treatment for the following condition: Had been ailing for a week or more, and from no apparent cause. Disinclined to go about, and complained constantly of feeling tired. No pain anywhere. No appetite. Bowels constipated. Sleeps a great deal during the day, but during the night is restlesss and cries out in his sleep. Temperature 100½°. Tongue coated. Urine scanty and high colored. No other indication of gastric or intestinal disorder, or of any organic disease.

Believing this case to be one of the disease under consideration rather than of catarrhal or other variety, it was treated with eight grains of calomel, repeated on the second day following. The child received no other treatment whatever. Three days from date of first visit the temperature was normal, and has remained so ever since.

Clinical experience has shown that many cases of fever may be aborted or overcome by drugs which possess antiseptic properties; especially is this the case in febrile conditions of intestinal origin. Whether these latter be due to microbes from without or from ptomaines generated within, the results of eliminative treatment are none the less of a most positive character, and have exercised a marked influence upon modern methods of medication. In typhoid and other fevers and inflammations of serous membranes—not excepting the peritoneum—we are to-day employing, to a greater or less extent, eliminative measures, and are relying much less than formerly upon opiates and the so-called antiphlogistic remedies.

Realizing the impossibility of diagnosticating the prodromic stages of any fever whatever, we cannot, of course, convince ourselves of the true value of abortive methods of treatment, yet, while we almost always note an alleviation of symptoms, we are at the same time, more or less confident of their power, at times, to cut short attacks of fever and inflammatory processes as well.

The eliminative treatment of disease has been practised to a great extent empirically and without special reference to the removal of effete matter from the system; yet while the effects of such drugs are not disputed, the proper appreciation of the real causes of disease may enable us to employ them more intelligently and with greater success.

PHTHISIS AND ITS NATURAL CURE.

By JOHN A. LANIGAN, M.D.,
HYDE PARK, MASS.

[Continued from the *Medical Register*, March 16, 1889.]

IN my last article on this subject I pointed out the manner in which I discovered an antagonism between rheumatism and tuberculosis; I now purpose to show more fully why such an antagonism must exist.

I incline to believe with most of the profession that the presence of lactic acid in the blood gives rise to those symptoms, the aggregate of which is known as rheumatism. At the first manifestation of the disease, examination of the blood of a rheumatic will disclose lactic acid; and whatever may have given rise to this state of the system is of little moment, for the rheumatism does not appear until this state is reached. Up to this time there may or may not have been a general malaise, but for that matter most diseases, if not all, must have an exciting cause, and the state of the system must be slightly below normal before disease can manifest itself. Nature is such a persistent and deadly enemy of disease that it will resist to the last any attack made upon its integrity, unless its efforts are rendered ineffectual by insufficient support.

For this reason I shall consider rheumatism as the result of the existence in the blood of lactic acid arising from some peculiar state of the system favoring its production. In like manner I would designate tuberculosis to be a nerve disease due to the spontaneous generation in the system of a bacillus from a preëxisting state favoring its development. The rheumatic state causes in some persons a deposit of some of the salts of the blood, particularly in the joints affected. Whether this be the process by which nature sometimes spontaneously effects a cure in tuberculosis, I am unable to say; but, if it is not

the exact, it certainly must be an analogous manner. Numerous cases are on record in which the tubercles have been changed into calcareous deposits by nature itself, and I know of no more rational explanation of the phenomenon than by presuming that nature had in some way generated the rheumatic poison, which in its turn destroyed the bacilli and deposited some of the salts of the blood where the tubercle previously existed.

It may seem here that I somewhat contradict a previous article to the effect that a tuberculous subject cannot have rheumatism; but I there meant to say that he cannot have rheumatism without destroying the bacilli of tuberculosis and hence the disease. Nature may by some unknown means set up rheumatism in a patient suffering from tuberculosis, and so bring about what we term a spontaneous cure. Many such cures, as I have said before, are known to the profession, but the means by which they are accomplished seem to remain a mystery. I think, however, that my explanation is a most rational one and certainly in accord with science. We read of many cases of consumption benefited and even cured by the use of koomiss and other such remedies, but upon close examination we shall find that all remedies which have ever been successful in tuberculosis have either contained, or could be readily converted into, lactic acid, the poison of rheumatism; and this, I believe, is the manner in which they prove beneficial. And even though lactic acid be a result of fermentation as some hold, this would in no way militate against my theory; for such fermentation may and very likely does take place in all the spontaneous cures which nature has effected, or art has brought about.

Moreover, lactic acid is known to be a decided solvent of tuberculous sputa, and so may act partly in this manner upon the mucous membrane of the diseased lungs. Of course it will be perceived that I am trying to give merely a satisfactory theoretical explanation of the manner cures are effected in this fell disease; for although it is positively known that such cures have taken place, yet how they were brought about no one that I have ever read has attempted to explain. One thing is certain, however, no cure of consumption can ever be effected unless the tubercle bacilli are destroyed.

"*Sublata causa tollitur effectur*" is an old maxim, never of truer application than in the present instance, and if we could imitate the remedy that nature has plainly pointed out to us, I say without hesitancy that we should soon be able to destroy the cause, and this disease would no more be formidable. One thing more which strikes me as peculiar is that the remedies advised in phthisis by the most eminent physicians: liquors, wines, milk, saccharine foods, syrups, malt, etc., are held to be decidedly prejudicial in rheumatism.

Thus when we consider fully the two states or diatheses we cannot help being struck by their total dissimilarity.

In the consumptive we have most frequently alkalinity of the blood; in the rheumatic there is acidity. The consumptive is always hopeful, the rheumatic despondent; there is nervous prostration or debility in the consumptive, in the rheumatic the reverse of this. In nearly every particular we find an opposite condition in the two diseases and everything pointing to a direct antagonism between them.

I am making some further investigations and experiments in this direction, which I shall be pleased to make known later.

The Polyclinic.

UNIVERSITY HOSPITAL.

THE first case I wish to show you this morning is this man, who met with a fall some time ago, but soon recovered sufficiently to return to his work as foreman in a steel works. While there he had symptoms of irregular fever. To-day he comes with a slight elevation of temperature—not marked; enormous spleen, which is undulating on its surface, hard, not painful, no fluctuation, and evidently a solid hypertrophy. He has had malaria. The spleen is often enlarged in malaria; in leukæmia in which the white cells of the blood are enormously increased and the red decreased. If associated with an enlarged spleen only, it is known as splenic leukæmia. In this case we have extreme anæmia, pallor, irregular fever, debility, and, on examination of the blood, an enormous increase in the white cells and decrease in the red. As to treatment, I will have him rest quietly in bed until fever is broken. I don't know what to do in his case—splenic leukæmia—for I do not know any remedy in the world that will cause it to run any other than its own regular course. Careful diet; avoidance of anything that will irritate the stomach; sodii salicylas to relieve fever and pains. He will not recover, unfortunately, as it is too far advanced.

PHTHISIS TUBERCULOSIS.

This woman, married, has a family which is perfectly healthy and has no history of tuberculosis. She has had malaria. Has been troubled with a cough, has night-sweats, pale, is wasted some, has a circumscribed catarrhal phenomena in upper lobe of left side; bulbous enlargement of balls of fingers. Four months ago she developed a laryngitis, with loss of voice. Both upper lobes of the lungs are diseased; large moist râles; almost cavernous respiration. Her laryngitis is associated with tubercular ulceration of the vocal cords and epiglottis. Sometimes food passes into the windpipe when she swallows. First of all, this woman must be spared all fatigue and have plenty of rest; meals should be prepared for her; extreme care that she will not catch cold. Her general health should be built up and promoted by rest and palatable food, and not by medicine, as she has a weak stomach. The great trouble is that physicians try to do too much and overdose their patients without considering the harm they are causing to the alimentary canal. Unless a patient like this can take and assimilate food the wasting is bound to go on; and let me say that in chronic diseases of all kinds tone up the stomach, for it is the citadel of life. She vomits after eating, and especially after coughing. Give her a diet of liquids at short intervals. Pepto-

nized milk, broth, gruel, soft boiled egg, expressed juice of meat every three hours or so, so that the stomach will not be full. Give oxalate of cerium, gr. j, in pill, four times a day after taking food. If this does not answer, give argenti nitratis., gr. ⅙; opii, gr. ½.—M. If still obstinate, give creasote with bismuth and soda. Once the stomach is in good order we will treat the lungs. I will have the following insufflating powder used for the laryngitis:

℞.—Iodoform . . . . . ʒij.
Acaciæ gum. pulv . . . . . ʒvi.
Morphinæ sulph . . . . . gr. ½.—M.

In this case you must treat it simply as a functional derangement. Give her plenty of good fresh air.

HYPOCHONDRIASIS.

This young man began complaining over one year ago of a pain that came in his back over the loins, and has, since then, consulted three or four doctors, but now is brought here by his original doctor. I find his heart's action sharp, but no valvular murmur, some tenderness over the abdomen. This is rather an anomalous case, for this man is very sensitive, much depressed in mind, and thinks entirely too much of himself. His attention has also been drawn to the fact that his left testicle hangs lower than the right, but every one of you knows this to be natural to all men. When this train of thought is started, without any knowledge to keep it straight, no telling how it may end—usually in an insane asylum, if they live long enough. A man came over six hundred miles for the purpose of asking me if his genitals were as large as normal, and was perfectly satisfied when assured that they were. These patients become cranky, crazy, or, as this man, go from one doctor to another and conjure up all sorts of imaginary symptoms.

This man has a certain amount of lithæmia, with a tendency to myalgic pains, and it is in this class of patients that you find hypochondriasis most common. They never believe what you tell them. Good advice is the best for this class of cases and not medicine. Carefully regulate diet and hygiene, and give them absolute assurance or proof of their soundness; stimulate the skin by friction. Nux vomica and nitro-muriatic acid will be of benefit. Get at the primary cause of the trouble and treat systematically.

—*Pepper.*

JEFFERSON COLLEGE.

HIP-JOINT DISEASE—A POINT IN DIAGNOSIS.

A CASE like the following will sometimes present itself to you. A young lady calls to inquire about her hip. She confesses to having had hip disease in childhood, to an abscess being lanced, and to final recovery. Could play as well as any of the girls, jump hoop, dance, go up and down stairs like other girls, and without lameness. Is sure both limbs move alike and are of equal length.

Now, in a case like this in which hip disease has not apparently been followed with all its dreaded sequelæ, it is well to convince the patient that she is in error about the relative movements of her two limbs before exposing her to the unpleasantness of an examination, and this can easily be done by asking her *how she puts on her shoes.* At this she will smile and confess that she does this in a manner wholly unlike other girls: that she sits down on the floor or turns her foot backward. The reason is manifest. The ordinary manœuvre in putting on a shoe is to rest the foot on the knee of the opposite limb. Now this requires flexion and rotation, and is impossible in a hip that has suffered from coxalgia. The confession that she puts her shoes on in a manner unlike that of other girls, disproves also the statement that she goes up and down stairs like other girls. There is in this, however, a qualification.—*Allis.*

HIP DISEASE ENFORCED—RECUMBENCY.

You will occasionally have a child brought to you with coxalgia in which horizontal rest with extension is the most rational treatment, but when you suggest it you will be met with the statement of the mother in the presence of the child: "It is impossible doctor, the child will not lie down, and cannot be made to do so." Now it is worse than worthless to argue with such a mother, and it is folly to prescribe. The child has grown to enjoy the mastery, and the mother does not propose to dispute it. Now I have found by experience an easy way to accomplish my purpose in such cases. I let the little fellow stand before me, strip him to his undershirt, and apply a plaster-of-Paris bandage about his waist, letting it come down well upon his pelvis. The little fellow will not object to this. He is now dressed and goes home, but he no sooner gets there than he finds it *impossible to sit up* with his plaster-of-Paris jacket on, and he succumbs to the only alternative. A few days horizontal rest in bed is sufficient to convince him of the advantage it affords, and now the plaster-of-Paris can be removed.—*Allis.*

COOPER HOSPITAL.

PARALYSIS FOLLOWING INJURIES TO THE SPINE.

ON account of the inaccessibility of the bodies of the vertebræ, it is difficult to determine at once the nature and extent of an injury to the spinal column. It is only by means of certain symptoms, of which paralysis and deformity are the most important, that a definite conclusion can be arrived at.

If, following a given injury to the spinal column, paralysis (both motor and sensory) of the limbs and portions of the body lying below the seat of injury is immediate, sharply defined at its upper border and constant, it is safe to infer that a fracture of one or more of the bodies of the vertebræ exist; especially is the diagnosis warranted if the paralysis is associated with a localized deformity of the spinal column.

If paralysis supervenes within a few hours after a given injury to the spine, without deformity or irregularity in the line of the spine, it is probably due to compression of the cord from an effusion of blood within the spinal canal. The blood-clot may have resulted from a rupture of the vessels on the inside or outside of the sheath of the cord. But suspended as the cord is within the dura mater, which is loosely connected with the bones by plexus of veins, the clot is perhaps more often on the outside of the theca of he cord.—*Godfrey.*

THE VIRGINIA EXAMINING BOARD.

WE have before us a pamphlet of sixteen pages, containing an account of the proceedings of this Board. Although there is no signature appended, nor anything to show by what authority the document is issued, we presume it is the official report of the Board, and will treat it as such. It states that the chief feature of the amended law is, that candidates must now appear before the Examining Board in regular session, instead of before three individual members at their homes. In cases of emergency, the President may appoint three members who can hold an examination, as a committee in session. This is certainly a commendable change; and substitutes a dignified method for one which was rather unconventional.

The applicant is required to answer at least three-fourths of all the questions satisfactorily, and he is to be rejected if he fails to answer satisfactorily one-third of the questions on any one branch.

This is a curious piece of bungling. Does it mean that if he reaches an average of 33⅓ per cent., it is sufficient, or is it 66⅔ he must attain?

The lists of questions are given; and appear to be well chosen. Certainly, we should not expect any man to receive a license who is not qualified to answer properly the eminently practical questions on therapeutics and practice.

The President's Address is mainly taken up with a discussion of the strictures upon the Board made by the medical journals, especially THE REGISTER and THE TIMES. The key is at last supplied by which the previous reports of the Board may be deciphered, and we can now ascertain just how many candidates have been before it from each college. The method is to subtract from the number of applicants the number of second applications, leaving the number of *first* examinations made. That this is an awkward way of putting the matter is evidenced by the fact that not one of the medical journals in the country solved it. Every one that quoted these reports, even wide-awake journals like the New York *Medical Record*, the *Association Journal*, the *Pittsburgh Review*, and others, gave the report literally, as it was printed. We are very glad, however, to relieve the Board of one of the strictures made upon it by the TIMES—that of having registered the Medico-Chirurgical College by another method than that used for other colleges. Until the present explanation was given, it was not possible to avoid the conclusion reached in our former remarks. It is now evident that in this particular we did the Board an injustice. We are sorry that we must add that in all other respects our objections to their actions were well-founded. Those advanced by Dr. Bryce in the *Southern Clinic* are practically admitted to be true, though a very lame attempt is made to gloss over the matter, by claiming that the President was deceived. In the discharge of an official duty, one is expected to use such due diligence as to avoid being deceived. Between carelessness and intentional error the difference is small.

The report goes on to state that no notification of the error regarding the Medico-Chirurgical College was received. The matter was noticed in THE TIMES, and a copy sent to the President of the Board. The receipt of Dr. Montgomery's letter calling attention to the same fact is acknowledged. It seems hardly possible that any one should want any further notification than this, even if the authorities of the Board could be ignorant that the medical press throughout the country was quoting their report, as showing that three candidates of the Philadelphia College had been rejected; two of them even after a second trial.

The remainder of this report is occupied by a malicious and wholly uncalled for attempt to find motives for the action of the Philadelphia journals which attacked the action of the Board. In a publication made some months ago, the action of the *Times* was attributed to its possessing a full page advertisement of the college in question. Age increases knowledge; and Dr. Nelson has now discovered that the *Times* is edited by a member of the Medico-Chirurgical Faculty. Truth and justice appear to be unknown quantities with the worthy President, who seems unable to comprehend that such motives could influence men to defend the object of an unjust attack. Those who are acquainted with the editor of the *Times* will not need to be told that his course would have been the same if the attack had been made upon the Jefferson or the University. His colleagues upon the committee appointed by the State Medical Society to urge the passage of the proposed bill creating a State Board of Medical Examiners, will not accuse him of lukewarmness in urging the passage of that act. The *Times* spent nearly $800 in furthering that measure, twice sending out special editions of 7000 copies to the Pennsylvania physicians, with editorials, etc., urging the passage of the Act. In fact, its defeat was probably due to the failure of the committee to

act upon the advice of this member, and urge the bill personally upon the members of the Legislature. This course was adopted by the irregulars, and by it they defeated the measure.

The charge that Dr. Shoemaker attacked the Virginia Board in order to defeat the Pennsylvania Act is a gross falsehood. At first, Dr. Shoemaker did not favor the bill; but after it had been fully discussed, he turned in and worked faithfully for its passage. No member of the Medico-Chirurgical Faculty labored more earnestly than Dr. Shoemaker to secure the united influence of the Faculty in favor of the bill. This statement can easily be verified by reference to those members who, like Dr. Garretson, opposed the bill throughout.

As to Dr. Keyser, that gentleman's course in regard to the creation of an Examining Board, from the time he first proposed it, has been so consistent that an attempt to rank him among its opponents merits no answer.

Out of this controversy this much good has come: that the Board has been forced to publish a correct report, showing the standing of the candidates from the various colleges in an intelligible manner.

DR. Dabney, in the Virginia *Medical Monthly* for April, contributes his answer to the charges of unfair dealing made against the Board by the Times. Laying aside the gross abuse and coarse insinuations in the article, which do not interest our readers and have no bearing upon the question in dispute, the only answer made by the champion of the Board is that the charge is not true. We have never called in question the action of the Board in rejecting the graduate of the Medico-Chirurgical College. No medical college in America is prepared to guarantee to all its graduates success in winning the endorsement of any Examining Board they may encounter. The special points to which we objected were that the Board announced *three* candidates as rejected on the *first* examination and two on the second; whereas there was but *one* candidate before the Board, who appeared and was rejected three times. Furthermore, we called attention to the fact that this very remarkable method of registration appeared to be employed only in the case of this college, while others were registered in another manner.

Take, for instance, the record of the College of Physicians and Surgeons, of Baltimore: 34 applicants, 10 rejections, 24 successful; 6 second applications, 2 successful, 4 rejected. How many candidates appeared from this school? According to the system adopted with the Philadelphia school, there were really only 28; of whom 24 succeeded and 4 failed; of whom 6 appeared a second time! Or, 28 candidates presented themselves, of whom 20 succeeded at the first trial and 4 at the second; leaving 8 rejections the first time and 2 at the second; the final result being 2 rejections after two trials, and 2 at the first which did not appear for a second.

Then take the Vanderbilt University: Record, 3 applicants, 1 rejection, 2 successes; 1 made second trial and succeeded. We have been puzzling over this for a long time, and do not see through the problem. There were three, or two, of whom one failed and two succeeded; and, perhaps, the one who failed was the one who succeeded at the second trial, and, perhaps, he was one of the two who succeeded. It's bewildering. The net result is that no mortal man can tell how many candidates have been before the Board, how many failed or anything whatever of the standing of the various colleges. We suppose that it will be admitted that failure means failure, and success stands for success; and that in comparing the various colleges, the percentage of their graduates who received the approval of the Board shows the degree of success attained. By the tables published, the University of Virginia suffered the rejection of 1 out of 33; Jefferson, 3 out of 12; Bellevue, 1 out of 6; University of New York, 2 out of 7; Vanderbilt, 1 out of 3; and the Medico-Chirurgical, 3 out of 3. Applying to this cipher the key furnished by the facts in regard to the latter, these figures resolve themselves into the following: University of Virginia, 1 out of 33; Jefferson, 1 out of 10; Bellevue, 0 out of 5; University of New York, 1 out of 6; Vanderbilt, 0 out of 2; Medico-Chirurgical, 1 out of 1. This, however, puts Bellevue and Vanderbilt above the Virginia school, and greatly lessens the percentage by which that village institution excels the city colleges, where medical teaching is rendered inefficient by their great clinical opportunities. The medical art is best learned by rote, like the multiplication table, and the superior advantages of a school which teaches from the book, without the drawbacks of clinical demonstrations, must be shown, at all hazzards.

But now that an intelligible record has been published, it will be seen that with all the advantages of a Board in sympathy with the Virginia University, that Institution really has made a poorer record than Vanderbilt; although this fact was completely covered up in the former report.

Annotations.

MISTAKEN ECONOMY.

ON account of the Governor's action in vetoing the appropriation for Will's Hospital, that institution has been compelled to reduce the number of its beds. This is a pity, for we know of no more deserving charity than that of Will's Hospital. Probably more patients from the State outside the city come to this hospital than to any other in the city, and no discrimination is practiced.

Only a day or two since we saw a poor woman from Reading, nearly blind, but whose eyes could be greatly benefited under proper care, refused admission for the simple reason that the hospital could not afford to take more patients.

When we consider what an incalculable blessing is

that of sight, and what untold misery is theirs who have lost that blessing. It seems to us that neither the Governor nor the State ought to begrudge the little money whereby the poor of Pennsylvania would be enabled to command that skill for which they cannot pay.

PRESS PROTECTION.

THE French medical journals have formed a Medical Press Association; the object of which is the protection of their common interests. The annual dues are thirty francs; or one-half for provincial members; and out of this sum are defrayed the expenses of the banquets at the quarterly meetings. The executive powers are lodged in the hands of three syndies, one of whom is elected annually to serve three years. The first syndies are M. M. Cézilly, Cornil, and de Rause; the representatives of the *Concours Médical*, *Journal de Connaissances Médicales praliques et de Pharmacologie*, and *Gazette Médicale de Paris*.

Society Notes.

SALPINGO-OVARITIS.

SALPINGO-OVARITIS was the subject of a paper before the American Medical Association at Newport, June 25, by DR. GEORGES APOSTOLI, of Paris, France. The following are his résumé and conclusions:

1. My electrical treatment of salpingo-ovaritis reaches back as far as the year 1882, and has been heretofore described under the name of treatment of perimetritis.

2. It comprises the methods of application, which, mentioned in the order of their increasing efficacy are: the faradic current of tension, the simple galvanic intra-uterine application, and the vaginal galvano-puncture.

3. Every electrical treatment always ought to be rigorously preceded by an antiseptic vaginal irrigation (of sublimate, carbolic acid, or naphthol). It will besides be most advantageous to keep the vagina closed between the treatments with gauze saturated with iodoform, sublimate or salol, for the purpose of maintaining perfect antisepsis, and to prevent, as far as possible, all sexual relations.

4. Confinement to bed, not obligatory in the light forms, will always aid the efficacy of the treatment. A rest of from one to several hours will be obligatory after every galvano-cauterization, and especially after every galvano-puncture.

5. Of the two localizations of the faradic current, which I advise, the vaginal and uterine—the uterine, with the aid of the bipolar sound, is the more efficient.

6. The faradic current of tension is only tolerable, and indicated in the acute and subacute forms, and the faradic current of quantity, which is less efficient and less tolerable, ought to be excluded, except in certain rare chronic cases, which are very old, in which it will be able to render some service.

7. The faradic current of tension is an excellent and rapid sedative, which calms the acute condition, diminishes the pain and nervous excitability, but remains powerless against the development of the inflammatory process.

8. The current of quantity will be able in certain chronic forms to aid in the absorption of exudates by stimulating the intestinal circulation.

9. Faradization ought here always to be applied in moderate doses, without shock and with a gentleness which increases in proportion as the condition is more acute.

10. The faradic treatment ought from the beginning generally to last from five to fifteen minutes daily, with a dose which increases gradually, and which ought not usually pass the limit of the individuals toleration.

11. Intra-uterine galvanization, or more properly chemical galvano-cauterization, will succeed often in itself in curing certain catarrhal salpingo-ovarites. It constitutes an excellent method of progressive and total destruction of the mucous membrane, which is always diseased in this case: of rendering heaithy the uterine cavity, aud of peripheric deviation.

12. It presents the following advantages over the use of the curette: it is absolutely harmless; it can be localized in the whole or in part of the uterine cavity; it is progressive, not violent, and never instantaneous; it is mathematically doseable and thus acts as may be desired; it is acid or alkaline at will; it is generally tolerable and requires no anæsthetic; it is easy of application and does not require an assistant; it does not condemn the patient to an enforced confinement to bed; it is not contra-indicated by any acute condition; it unites to a local superficial action, a trophic, general antiseptic and interpolar action.

13. The positive pole always causes less congestion than the negative, the latter bringing about resolution more rapidly; therefore the positive pole should usually be applied in the beginning, later giving place to the negative pole.

14. Every galvano-cauterization ought to be given in a small dose at first, also gently, in order to test the uterine and especially the peri-uterine susceptibility. The intensity will afterward increase with the tolerance of the patient and the clinical indications: beginning with twenty to forty milliampères, it will reach progressively the figure of one hundred to one hundred and fifty.

15. The treatment will take place once or twice a week, and the duration will vary from three to eight minutes, according to the circumstances.

16. Every salpingo-ovaritis which is not rapidly modified by the intra-uterine galvano-cauterization ought to be treated by the vaginal galvano-puncture.

17. The efficacy of the galvano-punctures is generally much greater than that of the galvano-cauterizations, as is affirmed by the patients and proved by my daily experience.

18. Every galvano-puncture should be scrupulously after the following general rules: To use a very small and sharp steel trocar. Never to bury it deeper than one centimeter at most. To avoid the anterior cul-de-sac and to make the puncture behind or at the

sides, upon the point of the inflammatory tumor which is most prominent in the vagina. Anæsthesia will be often necessary in galvano-punctures of high doses. To avoid the use of the speculum and to plunge the trocar through a long isulating cylinder of celluloid, after having previously explored the region with the index finger, in order to avoid any arterial pulsations. One or two weeks will intervene between the treatments by the galvano-puncture, and they should not usually be repeated until the reaction from the preceding has entirely disappeared.

The indication for galvano-punctures should be reserved for those cases alone in which the uterine appendages are near the vaginal wall. The average intensity of each sitting should vary between fifty and two hundred and fifty milliampères, and their respective duration should be from five to eight minutes.

19. The positive puncture will be generally indicated in the beginning as less dangerous and causing less congestion than the negative, and it will establish better the adhesions between the uterine appendages and the vaginal wall. The negative punctures, which generally produce more resolution in high doses, will aid in creating a vaginal fistula from the tumor in case of pyo-salpingitis.

20. Almost every salpingo-ovaritis will be amenable to an appropriate electrical treatment, which will be, above all, the conservative method of choice. This is sovereign in most of the catarrhal salpingites, calming, in the tuberculous salpingo-ovaritis, and capable of curing certain purulent salpingo-ovarites, because of the establishment of a vaginal drainage.

21. All electrical treatment followed by an intense or prolonged febrile reaction should be immediately suspended, or at least very much lessened, and this will sometimes decide the diagnosis of pyo-salpingitis. Pyo-salpingitis will only be amenable to treatment when it projects sufficiently into the vagina to permit evacuation with safety.

22. Every course of electrical treatment, whatever may be its duration, ought not cease until the patient declares herself symptomatically cured, and examination shows a considerable anatomical resolution.

23. All salpingo-ovarites will come under the domain of surgery, only when all the preceding electrical methods applied for a sufficiently long time, have been attended with failure.

24. Castration, which irretrievably mutilates women both physically and morally, which sometimes kills them, and which only cures permanently and definitely in about 20 or 25 per cent. of cases, ought to be an operation of necessity, never of choice, and should be considered as the last resource of therapeutics for the uterine appendages.

25. The electrical therapeutics, which I advise, are conservative, inoffensive, easy of application by every one, but do not pretend to produce a constant and radical cure of salpingo-ovaritis, and their best justification is found in the fact that a subsequent normal pregnancy is possible, which fact has been demonstrated in several of my patients.

Paris Letter.

THE EUPNŒTIC POWER OF MORPHINE.

FOR the laity and even for many doctors morphine is merely a calmant, acting by its analgesic power only; but it has also a respiratory action called eupnœtic (from eu, well, and pnœa, I breathe) that is most remarkable. Dr. Huchard, for years back, has insisted that morphine makes a person breathe, and some physicians use hypodermic injections of it in cases where they meet with intense dyspnœa. But, as a rule, this action of morphine is lost sight of in its all-powerful effect on pain; so that M. Fourrier does well, in a late article, to speak of this action of the drug. He cites a number of striking cases where the anti-dyspnœic action was seen.

One was an antero-selerosis case that could not find a moment of repose. Seated on a chair and his arms pressed against the back of it, the poor patient tried to breathe, but with little success. The face was in a state of cyanosis, and considerable œdema was present in the lower limbs. The important indication was, of course, to calm the dyspnœa. An injection of morphine did this rapidly, and digitalis in a few days afterwards completed the relief of the case. Another case was one of nervous asthma in a woman, who had a violent attack that was calmed in ten minutes by an injection of one centigramme of morphine. We simply call attention to this not-always-thought-of-power of morphine, which is applicable to a large number of cases. Another action of this important drug is *the elective power it has on the uterine organs*, and its therapeutical indications in this particular direction are given by Dr. Luteaud. According to this observer, morphine will diminish or even stop the menstrual function, and he gives some interesting cases taken from his experience. We all know the large use made of morphine in gynecological affections. There is hardly any inflammatory trouble of the pelvis that is not treated with it, and it is a common thing to see women becoming accustomed to its use, and ending, unfortunately, often in absolute morphiamaniacs. M. Luteaud having had under observation a number of such cases, was struck with the fact that the morphine they used stopped the courses. He found in eighteen cases that a minimum dose of twenty-five centigrammes would cause a cessation of the menses. He also found that it caused a suppression of all venereal desire. This same action has been shown by Dr. Jennings in men who were addicted to morphine, in some cases going so far as to cause complete incapacity for the sexual act. M. Luteaud concludes that there is in these facts an important therapeutical indication. As morphine suppresses menstruation, why not use it in cases of women who have some serious affection that calls for its suppression? Uterine fibroids are aggravated by the menses and cancer of the uterus as well; so that the indication seems to be to use morphine and suppress all hemorrhages in such cases, and in all painful affections of the womb.

Syphilitic Arthritis.—M. Kermisson, in an excellent clinic, shows that we should not class an articular

chronic arthritis until we know just what it is. The prevalent idea at present is to make all articular swellings into tubercular lesions, but this is an error, as there are other inflammations of the joints of a different nature; just as we have alongside of tubercular coxalgia, rheumatic coxalgia. There is first of all chronic arthritis from traumatism, others again from a propagation of some inflammation near by, and finally there is syphilitic arthritis. It is well then to search out what is the origin of every chronic joint trouble we see, so that we can separate the tubercular from other lesions. The patient presented by M. Kermisson was a woman of thirty-three, who came in for a chronic arthritis of the left knee. It had begun four years ago by a small movable tumor on the external side of the articulation. At first this did not trouble her, as she continued to go about; and it was only in December last that she saw a doctor, who prescribed vesication and afterwards cautery points, but without any good result. She then entered a hospital, where tincture iodine was used externally and sulphur baths given. On her entry into the Hôtel Dieu she presented the following signs: A swelling on the left knee from an effusion that was intra-synovial. There was no tension, only the soft consistence of a partly filled sack, so that it was quite possible to feel the epiphyses, which had kept their normal size. The tumor was found at the supero-external part of the knee, and was about the size of a walnut. It was movable, and the joint could be put through the usual movements without great pain. M. Kermisson at once said it was a syphilitic arthritis, as this is the only one of these lesions that presents so well-defined an induration with a localized seat, and with such an insidious method of growth. The patient, however, refused to admit any specific disease, but the application of Vigo's plaster and administration of Gibert's syrup caused a rapid cure. Immobilization is not needed, though some compression may be used to bring about resorption of the hydarthrosis that accompanies the trouble, but specific treatment with mercury will alone bring a cure in such cases. If there should be any muscular atrophy later, then massage, sulphur baths, and electricity may be called into play. The prognosis is favorable also, so that this affection is different in every way from the ordinary chronic articular troubles. The clinical points of difference are: The existence of one or more painful points on the joint, and at the same time a tumor which is limited in extent. This is often continuous with the bone, or it may be a subsynovial gumma. There is but little, if any, functional trouble here, no fixed attitude, no muscular contractions, and the hydarthrosis will be more or less pronounced. The knee is the joint most often attacked by syphilitic arthritis.

The General Action of Tobacco on the Organism.—Dr. Huchard, in his new volume of "Clinical Lectures," has a good deal to say on this subject. First of all in regard to the poisonous principles contained in the plant. Heubel has shown that the nicotine exists in the form of malate and citrate of nicotine, and Drysdale claimed that tobacco smoke contains as much as 30 grammes of nicotine for 4500 grammes of smoke. Le Bon follows by saying that Turkish tobacco contains prussic acid, and that Havana has another alkaloid called *collidine*, of which one-twentieth of a drop will kill a frog with symptoms of paralysis. The half-liquid matter that accumulates in the bowl of a pipe will kill a small animal in three-drop doses. The action of tobacco is upon the nervous centers and the pneumogastric nerves, and also on the vessels and the muscular system. As to the first: A few drops of nicotine instilled under the conjunctiva of an animal will kill at once. Eight drops will kill a horse with frightful general convulsions, and the muscles are found in such a state of tetanus that they seem to have lost all contractility. There is a remarkable action of habit in tobacco poisoning; an animal that is thrown into convulsions by one-half a drop one day, will require twice as much the next day; and so on in four or five days, four or five times as much. M. Huchard thinks that the action of tobacco poison is mostly on the medulla oblongata, as he saw two cases of bulbar paralysis from its use. It was Claude Bernard, who first showed the effects of tobacco on the vagus nerves. There is a sort of antagonism between the effects of tobacco and digitalis. The last diminishes the frequency of the heart's beats and increases their energy, and the first does the contrary, as under nicotine the pulse increases and loses its fulness and tension. The physiological action of nicotine explains the phenomena seen in man after abuse of tobacco. First, there is a dyspnœa called *nicotic asthma* with hiccough, and a sensation of thoracic constriction, and, in serious cases, stertorous respiration. There follows on this a sensation of anguish about the precordial region, and palpitation. This state Dr. Huchard proposes to call "*irritable heart.*" The action is not all on the nervous system as some would have it, for the muscular and vascular action is quite as important, if it is not more so. There is a vaso-constrictive action or retraction of the arterial system, consecutive to the augmentation of the arterial tension which is produced, and which is followed by a depletion of the arterial system. The effects of tobacco are similar to a galvanization of the great symphetetic nerve, and it is probable that nicotine acts on these vessels. The symptoms of tobacco intolerance are frequent in mitral disease, and they cause an angina that Dr. Huchard divides into several classes. He admits, however, that moderate use of tobacco in most persons is inoffensive, as the system readily takes on the habit of being poisoned; but at the same time a certain number of patients, such as those who are suffering from insufficient nutrition, alcoholism, intellectual and moral fatigue, anæmia, and above all the anæmic people who have some abnormal excitation of the vascular system; also the lymphatic and those who are obese, and, finally, those who have heart diseases, are all liable to have the anginas when they use tobacco to any great extent.

Glycosuria in the Normal State.—A considerable interest is now taken in diabetes, from the fact that a certain quantity of glucose is excreted in the physiological state. M. Quinquaud, who has studied the matter, says that the question has been much in dis-

pute, but after having made careful experiments he finds that the normal human organism really eliminates by the kidneys eighty centigrammes of a substance which is reducable and fermentable. This figure changes a little in some persons, but it does not very much, so that it can be stated as the mean quantity of glucose that is eliminated daily in human beings.

Medical Treatment of Uterine Fibroids.—Dr. Lucas Championmière, though a surgeon to the St. Louis Hospital, does not neglect medical treatment, and has tried ergotine with many other drugs recommended in the above trouble; but never had any good results until he used the *juniperus sabina.* This he gives for a long time in a fifty-centigramme dose per day, divided in several doses at intervals of three hours.

The treatment should extend for months, in some cases for years, giving a rest of one month after two months' use of the drug, and advising complete rest at the menstrual period. A good result was always obtained. The fibroid diminishes, constipation ceases, the pain goes away, the menses become regular. Even the bladder function is restored; patients that needed to urinate every two hours, doing so only twice or three times a day, under the sabina.

THOMAS LINN, M.D.

PARIS.

The Inquirer.

THE MORPHINE HABIT.

SOME four years since I suffered such tortures from neuralgia that I could gain relief only by morphine. To my alarm and surprise, I found after a time that I was unable to stop taking the drug.

Although I most earnestly wish again to be a free man, and have used every means in my power, yet I am still a victim. If it were not for my wife and children who are dependent for bread on my daily exertions, I should go to some institution; but as it is, I can afford neither the time nor the money. I take hypodermically from three to four drachms a week. To add to all the rest of my trouble, I am in constant dread that my patients and others will find it out, and that the discovery will hurt my practice. Now cannot somebody suggest some medicine or plan of treatment that will be likely to help me out of this gulf of despair?

Anxiously, M.D.

ALL THE WAY FROM TEXAS COMES THIS CREDIBLE STORY.—A child was bitten in the jugular vein by a rat and quickly bled to death. Some months after a rat was caught which cried like a baby, and had a strikingly human face. These peculiarities were easily explained by a local naturalist, who said that this rat was doubtless the offspring of the one that killed the baby, and that the phenomenon was due to the alteration in her milk, caused by the child's blood which she had sucked!

Book Reviews.

AMERICAN RESORTS: WITH NOTES UPON THEIR CLIMATE. By BUSHROD W. JAMES, A.M., M.D. Philadelphia and London: F. A. Davis, 1889. Octavo pp. 300, cloth. Price, $2.00.

The scope of medicine has become so extensive in late years that under the healing art is included everything ever known that may conduce to either the curing or the preventing of disease. The mass of knowledge is far too great for "one small head" to contain, so that the doctor must have at hand his books of reference.

Dr. James's work is, we think, both important and valuable, mentioning as it does, all known seaside and fresh water resorts, mountain resorts, summer and winter resorts. There is a chapter on "Mineral Springs," and one on "Trips upon Ocean, Lake, and River." In the first part of the book "Medical Climatology" and "Benefits and Dangers of Health Resorts" are treated of, and in the last, "Therapeutics. Dr. James concludes by giving a translation of that portion of Dr. Woeikof's "Die Klimate der Erde" relating to North and South America and the Atlantic Ocean. A large map of the United States accompanies the book.

TRANSACTIONS OF THE AMERICAN ORTHOPŒDIC ASSOCIATION. Vol. I. Published by the Association, 1889.

This is an interesting and neatly printed volume of some three hundred pages, embodying the Association's Constitution and By-laws, and the proceedings of its first and second annual meetings. The Association is composed of the leading orthopœdic surgeons of the country, and we should, therefore, expect the papers to be what they are—full of interest and value. Many of the articles are illustrated with plates showing the various apparatus, and deformities with their corrections. The edition is limited to five hundred copies.

AN ELEMENTARY TEXT-BOOK OF CHEMISTRY. By WILLIAM G. MIXTER, Professor of Chemistry in the Sheffield Scientific School of Yale University. New York: John Wiley & Sons, 15 Astor Place, 1889. Pp. 439. Price, $2.50.

In the general rage for making books, that for making text-books is well to the front. The number that have been written on every teachable branch within the last few years, is simply enormous, yet we do not decry the movement. We consider them all valuable; though each one may not be in itself, nevertheless it is of use as a guide-post to some other author. Comparing for a moment the absurd and inefficient text-books of our grandfathers with the modern works of art from which our children study, we are convinced of the improvement.

The present work seems to be commendable, both in matter and in form, for the purpose for which it is written—a text-book.

LECTURES ON BRIGHT'S DISEASE. By ROBERT SAUNDBY, M.D., Edin. New York: E. B. Treat, 1889. Pp. 290.

The chapters which this book contains were in the first place lectures, but these were rewritten and

elaborated, so as to be more suitable for book form. Although there is nothing particularly new brought forward, yet the work forms an addition to our knowledge of this important disease, by reason of the fact that a number of new cases are related and experiments described.

The subject is divided into three sections: 1. General pathology. 2. Clinical examination of the urine. 3. Bright's disease.

Just as physicians of the present day know that it is not necessary to predict an early grave for a patient afflicted with any and every heart lesion, so we are beginning to discover that albuminuria does not necessarily mean Bright's disease—it may be and frequently is of no moment. Dr. Saundby's work tends to make this fact more clear. We are pleased to see him recommend that tapping should not be done until it is absolutely necessary. The fluid is usually soon replaced, and the patient a loser by just that amount of an important constituent of his blood.

A commendable feature of the book is the author's custom of placing at the end of each chapter a summary, so that at a glance the reader may see what has there been set forth or maintained.

HANDBOOK OF MATERIA MEDICA, PHARMACY, AND THERAPEUTICS. By CUTHBERT BOWEN, A.B., M.D. Philadelphia and London: F. A. Davis. Pp. 366. Price, $1.40.

In these days of severe competition and hard study, when the medical student is compelled to devote from ten to twelve hours of his time to laboratory work, dissection, lectures, and clinics, he has so small a margin of the day left for actual study, that he is utterly unable to find the time to devote to the perusal of the larger text-books on the various branches of medicine and surgery, but is compelled to make use of smaller ones; and this need has given rise in late years to a multitude of manuals, aids, epitomes, and handbooks. They are a necessity, and have come to stay.

The present one is arranged in the form of questions and answers, so as to make it of still greater aid to the student in that trying moment of his life-examination, and seems to be so complete as to cover every contingency that may possibly arise during that ordeal.

AN ELEMENTARY TREATISE ON HUMAN ANATOMY. By JOSEPH LEIDY, M.D., L.L.D., Professor of Human and Comparative Anatomy and Zoology in the University of Pennsylvania, President of the Academy of Natural Sciences, and of the Faculty of the Wagner Free Institute of Sciences, Philadelphia. Second edition rewritten. Philadelphia: J. B. Lippincott Company, 1889. Price, $6.

It is now twenty-eight years since Prof. Leidy's "Treatise on Human Anatomy" was first presented to the professional world. The then already widespread reputation of the professor, in conjunction with the acknowledged merits of the work created a large and imperative demand for the book which soon exhausted the edition, and for years a copy could only be procured at a high premium, but now, after the lapse of over a quarter of a century, at the earnest solicitation of many of his admirers and students, Dr. Leidy has prepared this new edition, which is entirely rewritten, and in all respects worthy of the highest commendation.

A lifetime devoted to the study of human and comparative anatomy has rendered the distinguished author eminently fitted for the production of a work of this magnitude. With an eye single to the needs of the medical student he has rejected all superfluous material, and thus, together with the conciseness and precision which is characteristic of all of his writings, he has produced a volume which cannot fail to be recognized as a most systematic study of this conplex subject.

While, as a whole, the work is one of superior merit, there are several features in connection with it which are especially commendable and noteworthy. The most striking of these is the adoption of an anatomical nomenclature of the extremest simplicity with the view of facilitating the memorizing of the often difficult and bewildering technical terms. This is accomplished by substituting wherever it can be done, the English name for the Latin, by replacing the names of individuals when given to structures by more appropriate descriptive terms, by avoiding a multiplicity of terms when two or more are applied to a part. However, in order to overcome any confusion, and for assistance in reference, all the synonyms of the various tissues and organs, as they are studied, are retained and printed at the foot of each page. To this system of nomenclature does the work owe much of its inherent value.

Another interesting and valuable feature is the large proportion of original illustrations which abound throughout the work. Out of a total of four hundred and ninety-four, two hundred and one are original, either by the author or by Dr. Schmidt. While these are not as large nor as well adapted to the purpose of dissection as those in some of the larger and more comprehensive anatomies, they are still distinct and to the purpose, and it must be borne in mind that the work in hand is eminently a text-book and not a dissector.

Dr. Leidy is distinguished throughout the world as an original and untiring investigator, and in the present edition he has incorporated the result of his earnest, careful work of the past twenty-five years. All that will be necessary to prove the incalculable value of this feature of his book is to call attention to the light he has thrown upon that hitherto but dimly illuminated part of the human anatomy, the tympanum. Through his efforts the middle ear may now be studied with as great ease and clearness of apprehension as the other simpler portions of the body.

In conclusion we would recommend Dr. Leidy's book as one not only of inestimable value to the student, but as worthy of a place in the library of the oldest and most experienced practitioner.

ELECTRO-THERAPEUTICS OR ELECTRICITY IN ITS RELATION TO MEDICINE AND SURGERY. By WILLIAM HARVEY KING, M.D. A. L. Chatterton & Co., 78 Maiden Lane, N. Y.

This little work of 148 pages will prove of value to

the busy practitioner, who has not the time to study the complications of the more exhaustive works on this subject, but who wishes to know merely what to apply electricity for, when to apply it, what kind to make use of, and how to use it. These are the points Dr. King has had in view. The book is copiously illustrated.

Pamphlets.

Scarlatina Otitis, by Charles H. May, M.D., New York.

Medical Department of the Tulane University of Louisiana. Catalogue of 1889–90.

Therapeutics of the Gouty Diathesis, by Solomon Solis-Cohen, A.M., M.D., Philadelphia.

Fourth Annual Report of the Board of Managers of the Chinese American Union of Philahelphia.

A Résumé of Experience at the Aural Clinic of Prof. Herman Schwartze, in Halle, Germany, by Charles H. May, M.D., New York.

University of the City of New York, Medical Department. Forty-ninth Annual Announcement of Lectures and Catalogue, 1889–90.

A Clinical Study on Alopecia Areata and its Treatment, by L. Duncan Bulkley, A.M., M.D., New York.

Dr. Bulkley believes this disease not to be of local or parasitic origin, but that it is constitutional, and he has had the best results when he so treated it. Curiously enough it seems to be found to a greater extent, relatively speaking, among the better classes than among the lower; this fact is also opposed to its being of parasitical origin.

Horrors of Modern Matrimony: a Lecture. The lecture with this startling title is said to have been delivered before a certain Philosophical Society of Chicago, but if it was, we pity the society. The writer after wandering aimlessly about over a number of pages, finally concludes that matters are not as they should be, and that we are all going to the dogs, but he fails to suggest a remedy; unless it may be those pills of his, advertised on the back pages as competent to cure any ill or ailment known to any age, sex, clime or race.

On Unusual Methods of Acquiring Syphilis, with Reports of Cases, by L. Duncan Bulkley, A.M., M.D., New York.

In the course of this interesting paper Dr. Bulkley remarks that in spite of the common belief to the contrary, he has not been able to find an authenticated case where syphilis was contracted from a privy seat, and again he knows of only one instance in which the disease was gotten from holding a coin in the mouth, though one wonld think such a method not uncommon, on account of the frequent and filthy habit many women have of holding money in the mouth while making change.

Disease: Its cause. By G. M. Dewey, M.D., Detroit, Mich.

This title belongs to an effusion written in the form of verse, and probably intended for poetry. The humor in some parts of it is much broader than deep, and the vagaries of the rhythm are equalled only by the singularities in rhyme.

For instance, speaking of our mother Eve:

> On her own head the judgment brung,
> Of sorrow when she bore her young.

And:

> Far more respect of old was given,
> To the cadaver than the liven.

"Dyspepsia" and "catalepsy" are also forced to rhyme, as is also "Koch" with "mock."

THE new cigarette law is said to be a dead letter in this city.

Gleanings.

DEATH FOLLOWING THE SUSPENSION METHOD.—Dr. Gorecki reports the following case:

A man, forty years of age, suffering from ataxia for five years, having read an article in the daily papers about the suspension method, sent out and bought the apparatus and resolved to follow the treatment. His malady had made rapid progress, as he suffered from almost total paraplegia, but his intellect was unimpaired. He caused himself to be suspended by his servant two or three minutes each day, and as the first seven occasions were followed by the usual benefit, he congratulated himself on his progress.

At the end of the eighth *séance* he had lost speech and hearing, but preserved sight, intelligence, and movement. Dr. Callamand was sent for, and tried stimulation, subcutaneous injections of ether, etc. Deglutition was impossible, and notwithstanding every care the condition of the patient became more grave. The same night as the accident the power of sight was lost, and the paralysis extended rapidly to the arms and thoracic muscles, death following in twenty-four hours from suffocation. This, we believe, is the first fatal accident following this treatment, which, in this case, was instituted without medical supervision.—*La France Médicale.*

TREATMENT OF OBSTINATE VOMITING.—

(1) ℞.—Tincture of iodine . . . . . 16 drops.
Distilled water . . . . . 60 grammes.—M.
Sig.—A tablespoonful every half hour.

(2) RANDOLPH'S MIXTURE:
℞.—Creasote . . . . . 20 drops.
Acetic acid . . . . . 40 "
Sulphate of morphine . . 0 gr. ½.
Distilled water . . . . . 60 grammes.—M.
Sig.—Two or three tablespoonfuls every half hour.

(3) ℞.—Phenic acid . . . . . 1 drop.
Chloroform . . . . . 3 drops.
Alcohol . . . . . 20 "
Distilled water . . . . . 15 grammes.—M.
Sig.—For one dose; to be repeated one-half hour late if necessary. Especially useful in Asiatic cholera.

(4) CHOLERA INFANTUM:
℞.—Phenic acid . . . . . 25 drops.
Alcohol . . . . . 25 "
Peppermint water . . . . 45 grammes.
Mucilage of gum arabic,
Syrup of poppy . . . . āā 15 drops.—M.
Sig.—A tablespoonful every two hours.

(5) ASIATIC CHOLERA:
℞.—Chlorohydrate of morphine . 0 gr. 15.
Subcutaneous injection.

(6) VOMITING OF PREGNANCY:
(*a*) ℞.—Elixir of opium . . . . . 30 drops.
Bromide of potassium . . . 1 gr. 8.
Water . . . . . 60 grammes.
Sig.—For rectal injection.

(*b*) DUJARDIN BEAUMETZ:
℞.—Chlorohydrate of cocaine . . 0 gr. 42.
Distilled Water . . . . . 300 grammes.—M.
Sig.—Take a teaspoonful every hour. To avoid the vertigo remain in the recumbent position.

(*c*) ℞.—Fluid extract of viburnum . 3 gr. 75.
Sig.—To be taken at successive times

—*La France Médicale.*

ANTISEPTIC TREATMENT OF TYPHOID FEVER.—Prof. Bruchard commences his treatment by the use of calomel, two centigrammes a day for four days.

As soon as the rectal temperature passes 40° C. cold baths are employed, 2° less than the body temperature. Every ten minutes the temperature of the bath is to be reduced until it reaches 30°. Not more than eight are to be given in twenty-four hours.

These baths are to maintain the temperature of the body from 37° to 37.5°.

If the baths are not sufficient to reduce the temperature, we employ the sulphate of quinine, which is an excellent microbicide.

We commence with two grammes in the twenty-four hours, and gradually reduce the dose until the temperature is 37° in the morning and 38° at night.

Dr. Bruchard uses the following internal treatment:

℞.—Naphthol,
Salicylate of bismuth . . . . . āā 5 grammes.
Sig.—Divide in ten parts; one to be taken every hour.

The result of this mixed treatment is most satisfactory. It responds to all indications.

—*La Tribune Médicale.*

FOR THE AGREEABLE ADMINISTRATION OF COD-LIVER OIL (Seig.).—

℞.—Cod-liver oil . . . . . 2000 grammes.
Creasote . . . . . 2 gr. 50.
Saccharine . . . . . 0 gr. 16.

The odor of this solution resembles that of smoked meat.—*Revue de Thérapeutique.*

ANTIDYSPEPTIC POTION (Bucquoy).—

℞.—Fowler's solution . . . . . 1 gramme.
Tincture of nux vomica . . . . . 2 grammes.
Syrup of tar . . . . . 300 "
Sig.—A tablespoonful before meals.

—*Revue de Thérapeutique.*

EXPECTORANT PILLS (Lépine).—

℞.—Terpine . . . . . 3 grammes.
White sugar,
Gum arabic . . . . . āā q. s.
Sig.—For thirty pills; three a day.

—*Revue de Thérapeutique.*

FOR DIFFICULT DENTITION.—

℞.—Hydrochlorate of cocaine . . . . 0.05 centigram.
Bromide of potassium . . . . . 0.50 "
Distilled water,
Glycerin . . . . . āā 10 grammes.
Sig.—To be applied with the finger.

—*La Tribune Médicale.*

TREATMENT OF LEG ULCERS.—Dr. Appenroah mentions a new method for the treatment of leg ulcers. After having washed the leg, light friction is used from the knee downward. This massage has the effect of producing an exudation of lymph in the ulcer. Granulations soon appear and a cure follows this process. The Doctor recommends pure lanoline as a dressing, as antiseptic substances are apt to produce irritation.—*L'Année Médicale de Caen.*

XERODERMA PIGMENTOSUM.—Anderson (*British Med. Jour.*) reports a case of this rare skin disease. A colored plate accompanies the note.

EXCISION OF CLAVICLE.—Jessett (London *Lancet*) reports a case of excision of this entire bone for a sarcoma. This is the sixteenth time the operation has been performed.

UTERINE MEDICINES.—Davies (London *Lancet*) considers uterines, so-called, as eminently unreliable in their effects, but he says that for an efficient emmenogogue nothing has yielded, in his hands, results so good as a combination of canlophyllin and pulsatilla.

SUPPRESSION OF RABIES.—The *Brit. Med. Jour.* believes that if the ideas advanced by the Society for the Prevention of Hydrophobia were carried out, cases of this disease could be reduced to zero, and shows that hydrophobia has been rare or frequent just in proportion to the precautions taken against rabies.

TYPHOID FEVER AND MILK.—The London *Lancet* mentions a sudden outbreak of typhoid fever, the cause of which was supposedly traced back to a dairy where the proprietor's son was convalescing from that disease. At any rate, when the distribution of the milk was stopped, the disease came to an end.

WATER IN THE LUNGS.—Bowles (London *Lancet*) says that contrary to the general belief that water does not enter the lungs of those drowned, on account of closure of the epiglottis, he has found water a number of times in the lungs of both animals and human beings who died by drowning, and therefore holds that the Sylvester method of resuscitation is not to be relied on.

IMPOTENTIA VIRILIS.—Prof. Fuerbringer, before the Congress for Internal Medicine, held at Wiesbaden April 15—18, 1889, remarked as follows: As is well known, *impotentia generandi* must be distinguished from *impotentia cœundi*, and it is the latter form, denominated by Rockwell and Hammond as *sexual neurasthenia*, which is now under consideration. Aside from mechanical interference with erection due to abnormalities of the corpus cavenosum and corpus spongiosum of various causation, we have to do in most cases with nervous impotency accompanied by seminal loss, where the genitalia themselves are intact; and here belong the cases of purely psychical or moral impotency, which impotency often constitutes the sole symptom of the neurasthenia. 200 cases of *impotentia cœundi*, and during the same time 100 cases of *impotentia generandi* have been observed—all in private practice. Of 15,000 hospital patients (Friedrichshain) only 2 complained of this functional disturbance, which is by no means to be referred to a variety of this disease among the class of people frequenting the hospital, but rather to their ignorance and indolence as to several affairs. The youngest of the 200 patients was eighteen, the oldest fifty-two years of age, about half of them being in their fourth

decade. As to occupation the majority of them were merchants, officers and physicians, the merchants notably Russians and Jews; and the minority were theologians and teachers, though, as is well known, these form the largest contingent for masturbation and spermatorrhœa.

As to ætiology the anamnesis shows 28 per cent. to be caused by onanism, 38 by gonorrhœa, 13 by onanism and gonorrhœa, 10 by excessive venery, 11 by hereditary debility. *Coitus interruptus* or *reservatus* are without influence. The neurasthenic phenomena accompanying inpotency are headache, dyspepsia, palpitation of the heart, depression, more rarely hyperasthesia of the genitals, frequently varicocele. In general it is not the *unnatural* gratification of the sexual desire so much as the *excessive* venery which leads to impotence.

Corresponding with the four factors of cohabitation (*libido*, *erectio*, *ejaculatio* and *orgasmus*) four forms of impotentia cœundi are distinguished.

1. All the four factors are diminished, particularly the second. This, a state parallel with senile involution, can the more easily be endured by the patient, unless the wife, possessing a strong sexual appetite, drives him to the physician. Sometimes, however, it is just the *indifference* of the wife which produces this form of impotence. Under such conditions it is more proper to speak of *impotentia* or *impudentia muliebris* than of impotentia virilis.

2. The first factor remains normal or is increased, while the other three are impaired. The prognosis of this form is bad; for besides the severe headache, etc., the patient suffers the tortures of Tantalus in having lost the capacity for gratifying his sexual desires.

3. This form is characterized by normal erections, but at the same time by precipitated ejaculations without orgasm, thus bordering on diurnal pollutions.

4. The first and third factors remain, but erection can be brought about only by intense peripheral and mechanical, not by cerebral, stimuli, reminding one of that form of impotence caused by intellectual overwork.

The *diagnosis* of impotentia cœundi must be differentiated from the impotence conditioned by various general affections. In each case therefore the urine must be examined, for albumen and sugar, and symptoms of tabes dorsalis, brain tumors, syphilitic gummata, etc., must be rigidly excluded.

The *prognosis* depends upon the degree of neurasthenia, and in general is not very favorable. One-third of the cases were cured, one-third improved, and one-third were discharged unimproved, or worse.

The *treatment* must be chiefly a general one; local treatment, in the purely neurasthenic cases is unconditionally to be rejected. Above all things physical and psychical rest and total sexual abstinence must be insisted on. Travelling, electricity, massage, hydro-therapeutics, and general hygiene, particularly according to the *Mitchell-Playfair* method, is recommended. Marriage cannot be unconditionally prohibited, but its propriety should in each individual case be decided by the physician.

—*Wiener Med. Presse.*

Medical News and Miscellany.

VETERINARY surgeons and physicians must now register.

DR. BACHE MCKEE EMMET, of New York, summers at Newport.

DR. STEPHEN SMITH BURT goes up the Hudson during his outing.

DR. D. B. ST. JOHN ROOSA, New York, was to sail for Europe on June 26.

TWO sailors are reported at the Marine Hospital station sick of yellow fever.

DR. CLARENCE C. RICE, of New York, has arranged for a European trip, beginning July 10.

THE brain of Laura Bridgman has been preserved and will be subjected to careful microscopic examination.

RUSSIA will allow women to practice medicine, but their services must be confined to women and children.

DR. GEO. B. FOWLER, of New York, favors Bay Harbor, at the extreme eastern end of Long Island, this year.

DECREASING.—Strangely enough the number of medical men in France is on the decrease: 18,000 in 1848, 11,000 now.

DR. F. KAMMERER announces that he will operate at the German Hospital, New York, every day, but Wednesdays, at 2.30 P. M.

DR. JAMES W. MCLANE has been chosen to succeed the late Dr. Dalton as president of the College of Physicians and Surgeons, New York.

NAPLES is to be completely renovated with a view to proper sanitation. It is intended to demolish 17,000 houses in the course of the work.

DR. MORRIS, in making sanitary investigations along the Philadelphia docks, found so many stenches that he was twice prostrated with colic.

ONE Watson Goodspeed who desired to emulate Dr. Tanner's fasting exploit, has made such good speed that he nevermore will eat an earthly bite.

SMALLPOX extends over so much of one of the rural districts of England, that a wooden hospital has been built which can be moved from place to place.

DR. WM. OLIVER MOORE is becoming a confirmed Long Islander, and favors Bayport on the Great South Bay, where he is learning to be very nautical.

DR. WALTER L. CARR is holding clinics in diseases of children this summer on Tuesdays, Thursdays and Saturdays at St. Mary's Hospital, 407 West Thirty-fourth Street, New York.

JOHN KENNEDY says that a needle, which five months ago he ran into his right foot, lately came out of the other foot after having made the round trip. This sounds plausible enough.

At the commencement of Rutger's College, N. J., held on June 18, the degree of A.M. was conferred on Dr. H. Genet Taylor, in virtue of his position as President of the New Jersey Medical Society.

According to a daily paper, two doctors at Columbia removed from a man's face the breech of a gun, which had entered in three pieces. Either the patient had a large face or the gun a small breech.

Apropos of lepers, a sympathetic reporter in one of our daily papers says that a lot of learned men met the other evening and "gloated" over two poor creatures who had been induced to make an exhibition of themselves.

English people knew nothing about leprosy, until some one offered to endow a leprosy ward in memory of Father Damien; then quite a shock was given them when they learned that there are some twenty lepers in England.

It is something of a blot on Philadelphia that it should have more cases of death from typhoid fever to the 1,000,000 than any other city. The cause of this fever and the manner of its prevention are so well known, that so large a mortality should not exist.

A physician in a small New Jersey town is likely to get into the courts, because patients belonging to his private insane asylum meander about the town blowing kisses at the ladies and occasionally manifesting a pardonable desire to hug the prettiest of them.

In spite of their care at the Philadelphia Almshouse, the mortality among foundling infants is great, 22 out of 36 having died during the last year.

It is now intended to send them out of the city during the summer to see what effect the country will have.

Politics, as sometimes happens, took a city's sanitary welfare in its grip last week, when a deadlock in the Long Island Civil Government rendered impossible the organization of the Health Board of that place at a time when diphtheria was threatening to become epidemic.

Drs. Crawford, of Wilkesbarre, Davidson, of Cambria, and Barret, of Pittston, form the new Pension Board for the Twelfth Congressional District. Corporal Tanner has done himself honor in the selection of this Board, which commands the respect of the entire community.

New Jersey Medical Society.—The one hundred and twenty-third annual meeting of the Medical Society of New Jersey was held at Asbury Park last week with about one hundred and fifty physicians in attendance. Dr. H. Genet Taylor, of Camden, president of the society, occupied the chair.

The adulteration of foods is so common that we are not surprised to learn that honey is affected by the practice. Combs made of paraffine are filled with glucose, and the combination sold as simon-pure honey; whilst the heretofore busy bee sits on his front steps with his hands in his pockets.

Dr. M. J. White, Superintendent of the Milwaukee Asylum for the Insane, announces that the position of second assistant physician at that institution will be vacant on August 1, when Dr. Scovel, who at present holds the office, retires. A German American is especially desired.

The custom of drinking large quantities of ice water is certainly pernicious, but if those who persist in drinking it are advised to hold each mouthful in the mouth for a few moments, the temperature will be increased, the agreeable sensation not lost, and the stomach will receive much less of a shock.

The phlegmatic Germans look askance at the glowing reports of French medical successes by hypnotism. Dr. Moll, an advocate of hypnotism, delivered a lecture before the Berlin Medical Society, detailing a number of cases; but the reporter says: "the majority of Dr. Moll's hearers remained unconvinced."

A Descendant of Sindbad's.—A doctor in Colorado relates that two men who wished him to set a broken leg, took him blindfolded to a cave, the walls of which were "yellow like gold." After the operation he casually picked up a little piece of rock, which the assayers tell him will run $60,000 to the ton.

There will be a vacancy in the house staff of the Manhattan General Hospital at Tenth Avenue and One Hundred and Thirtieth Street, New York, on July 1. Candidates for its position were examined on June 12, but the choice of Dr. F. H. White, Secretary of the Medical Board, was not announced at the time this was written.

The New York Post-graduate Medical School and Hospital has just finished the most prosperous season of its career. Among the professors and instructors it has added to its *corps* this spring are Professor Ripley and Dr. H. J. Baldt. Dr. Emerson, the attending physician to the Manhatten Eye and Ear Hospital, was appointed to a professorship at the Post-graduate a few weeks ago.

Medico-Military Society.—At a meeting held at Asbury Park, N. J., June 18, a society of medical officers was organized to include in its membership those who have served and those who are now serving in the military service, under commissions issued by the Governors of New Jersey; and, also, those medical officers who served in the late war under commissions of a corresponding rank issued by the War and Navy Departments of the General Government.

The following officers of the Society were elected: President, Surgeon-General J. D. McGill; First Vice-President, Dr. J. H. H. Love, Surgeon 13th Reg. N. J. V.; Second Vice-President, Dr. H. Genet Taylor, Assistant-Surgeon 8th Reg. N. J. V.; Secretary, Dr. E. L. B. Godfrey, Surgeon 6th Reg. N. G. N. J.; Treasurer, Dr. J. D. Osborn, Surgeon 4th Reg. N. J. V.

A meeting to complete the organization will be held at the State Encampment, Sea Girt, in July.

Dr. D. Strock presided at the last meeting of the Camden City Medical Society. Dr. W. A. Davis read a paper on "Typhlitis and Peri-typhlitis," which was discussed by Drs. A. M. Mecray, D. Benjamin, G. T. Robinson and others. Dr. George T. Robinson made a report of his experiments with "oleite," which was generally discussed. Dr. Harry Jarrett was unanimously elected a member.

At the 123d Annual Meeting of the Medical Society of New Jersey the following officers were elected:

President, B. A. Watson, M.D., Jersey City; First Vice-President, James S. Green, M.D., Elizabeth; Second Vice-President, E. J. Marsh, M.D., Patterson; Third Vice-President, George T. Welch, M.D., Keyport; Corresponding Secretary, William Elmer, M.D., Trenton; Recording Secretary, William Pierson, M.D., Orange; Treasurer, W. W. L. Philips, M.D., Trenton; Standing Committee, T. J. Smith, M.D., Bridgeton; D. C. English, M.D., New Brunswick, and J. G. Ryerson, M.D., Boonton.

Essayest for the next meeting, E. L. B. Godfrey, M.D., Camden.

The Society will hold its next meeting at Schooley's Mountain.

The members of the New York Academy of Medicine are much elated over the fact that the plans for their proposed new building are assuming definite shape. Their future home will be located on the north side of West Forty-third Street, near Fifth Avenue, it will be 75 feet wide by 100 feet and 5 inches deep. The plans have been submitted and approved, and the work of excavating has already begun. The building will have four-and-one-half stories, and will be practically fire-proof. Besides the library and the large assembly room, the most important feature of a home for the Academy of Medicine, there will be a dining room, where the members will occasionally meet for dietetic experiments, purely in the interests of science. These experiments will undoubtedly be conducted in a comprehensive and exhaustive manner. There are to be rooms elaborately equipped for photographic and laboratory purposes, an elevator, and all other desirable modern conveniences. The ground cost the Academy $90,000, and the building, without fixtures, will cost $130,000 more. The sale of the present building of the Academy, at a fair valuation, will nearly free the Academy from the indebtedness of its new venture.

Army, Navy & Marine Hospital Service.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service for the two weeks ended June 24, 1889.

Hartcuff, Albart, Major and Surgeon. Is relieved from duty at Fort Hamilton, N. Y., by direction of the Acting Secretary of War, and ordered to Fort Omaha, Neb.

Brown, J. M., Major and Surgeon. Relieved from duty at Fort Omaha, Neb., and ordered to Fort Meade, Dak.

Shannon, W. C., Captain and Assistaut-Surgeon. Relieved from Fort Meade, Dak., and ordered to Fort Yates, Dak.

Ives, Francis J., First Lieutenant and Assistant-Surgeon. Relieved from duty at Fort D. A. Russell, Wyo., and ordered to Fort Lyon, Cal.

Philips, J. L., Captain and Assistant-Surgeon. Relieved from duty at Fort Lyon, Cal., and ordered to Fort Crawford, Colo.

McCaw, Walter D., First Lieutenant and Assistant-Surgeon. Relieved from duty at Fort Crawford, Colo, and ordered to Fort McPherson, Atlanta, Ga. Par. 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

Gibson, Robert J., Captain and Assistant-Surgeon (Fort Trumbull, Conn.), is designated as Medical Officer for the encampment, at Fisher's Island, N. Y., and he will proceed to Fisher's Island, N. Y., August 1, 1889, and report to the commanding officer for duty at that post. Par. 5, S. O. 133, Headquarters Division of the Atlantic, June 13, 1889.

Gandy, Charles M., Captain and Assistant-Surgeon. Upon the abandonment of the post of Fort Concho, Tex., will report in person to the commanding officer, Fort Clark, Tex., for duty at that station, to relieve First Lieutenant Ogden Rafferty, Assistant-Surgeon, reporting also by letter to the commanding general, Department of Texas. Par. 7, S. O. 133, A. G. O., Washington, June 10, 1889.

Raferty, Ogden, First Lieutenant and Assistant-Surgeon. On being relieved by Captain Gandy, will report for duty to the commanding officer, San Antonio, Tex., reporting also by letter to the commanding general, Department of Texas. Par. 7, S. O. 133, A. G. O., Washington, June 10, 1889.

Wales, Philip G., First Lieutenant and Assistant-Surgeon (recently appointed). Will proceed from this city to the Presidio of San Francisco, Cal., by direction of the Acting Secretary of War, and report for duty to the commanding officer of that post, reporting also by letter to the commanding general, Division of the Pacific and Department of California. Par. 3, S. O. 132, A. G. O., June 8, 1889.

Ten Eyck, Benjamin L., First Lieutenant and Assistant-Surgeon (recently appointed). Will proceed from New York City to Fort Leavenworth, Kan., by direction of the Acting Secretary of War, and report for duty to the commanding officer of that post. Par. 2, S. O. 138, A. G. O., Washington, D. C., June 15, 1889.

Forwood, William H., Major and Surgeon. The extension of leave of absence on Surgeon's certificate of disability, by direction of the Secretary of War, granted in S. O. 118, May 22, 1889, from this office, is further extended four months. Par. 14, S. O. 142, A. G. O., Washington, June 20, 1889.

Carson, J. K., Major and Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. Par. 2, S. O. 65, Headquarters Department of the Columbia.

Fisher, Walter W. R., Captain and Assistant-Surgeon. The leave of absence for one month granted by S. O. 30, c. s., Department of California, and extended fifteen days by par. 3, S. O. 37, c. s., from these headquarters, is further extended fifteen days. Par. 1, S. O. 41, Headquarters Division of the Pacific, San Francisco, Cal., June 12, 1889.

Gardiner, Jno. de B. W., Captain and Assistant-Surgeon. Relieved from duty at Fort Leavenworth, Kan., by direction of the Acting Secretary of War, and ordered to Fort Reno, Ind. Ty.

Wales, P. G., First Lieutenant and Assistant-Surgeon. Is directed, par. 3, S. O. 132, June 8, 1889, A. G. O., to report to Fort Huachuca, Ariz., for duty in place of Presidio of San Francisco, Cal.

Wyeth, M. C., Captain and Assistant-Surgeon. Relieved from duty at Fort Huachuca, Ariz., and ordered to Fort McDowell, Ariz.

Wood, Leonard, First Lieutenant and Assistant-Surgeon. Relieved from duty at Fort McDowell, Ariz., and ordered to Post of San Francisco, Cal. Par. 2, S. O. 138, A. G. O., June 15, 1889.

Harris, Henry S. T., First Lieutenant and Assistant-Surgeon. Is granted leave of absence for two months, by direction of the Acting Secretary of War. Par. 13, S. O. 140, A. G. O., June 18, 1889.

Changes in the Medical Corps of the U. S. Navy for the week ending June 22, 1889.

Beardsley, Grove S., Medical Inspector. Granted a year's leave of absence, with permission to leave the United States.

Ferebee, N. M., Surgeon. Detached from special duty at Naval Academy, and wait orders.

Rothgauger, George, Assistant-Surgeon. Ordered to the Naval Hospital at Mare Island, Cal.

SODIUM SILICO-FLUORIDE.

(Prize Thesis, presented to the Medico-Chirurgical College of Philadelphia, 1889.)

BY JOHN W. CROSKEY, M.D.,
PHILADELPHIA.

SODIUM SILICO-FLUORIDE was introduced to the medical profession in this country by Mr. Frank Rosengarten of the firm of Messrs. Rosengarten & Sons, his attention having been called to this drug by the experiments of Mr. William Thomson, F.B.S.C., F.C.S., of the Royal Institution, Manchester, England, he having experimented with a number of chemicals to demonstrate their antiseptic properties.

The ones he found possessing the most remarkable antiseptic properties were the compounds of fluorine, hydro-fluoric acid and the acid and neutral fluorides of sodium, potassium and ammonium, and the fluosilicates of these bases. Of the compounds, he found fluosilicate of sodium the one which, for the general purposes of an antiseptic, was perhaps the best suited.

He claims that this salt is not poisonous, has no smell, and is sparingly soluble in water. Having obtained some of this salt from Messrs. Rosengarten & Sons, I found upon examination that it is a fine, white powder, of slightly saline acid taste, perfectly inodorous, seven grains of the salt dissolving in each fluidounce of water.

To test the solubility, thirty grains of the salt were taken and added to two fluid-ounces of distilled water, the temperature of which was 64° F. After shaking for five minutes, which raised the temperature of the water 2°, I emptied the solution upon a piece of filter-paper, the weight of which was twenty-three grains. After all the solution had passed through the filter, I evaporated the residue to dryness. I then set the paper and powder aside, so that it might resume its normal hygroscopic condition. Upon weighing the filter and residuum, I found the combined weight to be thirty-nine grains. Deducting the weight of the filter, twenty-three grains, left of the salt remaining undissolved, sixteen grains. As I originally had thirty grains, the two ounces of water appear to have absorbed fourteen grains, or seven grains of the salt to each fluid-ounce of distilled water, at a temperature of 64° F. In this experiment only one-half drachm of the original water was lost by evaporation. So, I think it is safe to say that the solubility of sodium silico-fluoride is seven grains to the fluid-ounce of distilled water, or 1.4 per cent. To ascertain if the salt would be more soluble at a higher temperature, the above experiment was repeated, heating the solution to the boiling-point, 212° F. The solution was then allowed to cool to a temperature of 64° F., and was then placed upon a piece of filter-paper weighing twenty grains. After allowing the solution to pass through the filter, after being dried it was again weighed and found to weigh thirty-

two grains. Taking the weight of the filter, at twenty grains, I would have undissolved twelve grains of the salt. This would make the amount taken up by the two ounces of water, at a temperature of 212° F., eighteen grains, or nine grains to the ounce. This solution did not remain clear like the former for in about four hours' time it threw down a flocculent white precipitate. These solutions gave me an acid reaction to blue litmus paper; but while giving an acid reaction, it could not be considered chemically an acid salt, the composition being Na_2SiF_6.

Sodium silico-fluoride is formed by the simultaneous production of hydro-fluoric acid and hydro-silicic acid. A mixture of sand and fluor spar is treated with concentrated sulphuric acid in a suitable vessel, whereupon the acid combines with the bases with which the alloys are combined, forming sulphates and silicic acid in the form of gas. This gas is passed into a vessel containing water. As the saturation is complete, and after standing the precipitate has settled, the clear supernatant solution is decanted into another vessel. After assaying to determine the quantity of hydro-fluosilicic acid in solution, the chemical equivalent of soda bicarbonate in solution is added, when a copious precipitate of sodium silico-fluoride ensues. If an effort be made to neutralize, by adding soda bicarbonate till litmus paper turns blue, the equivalent of silica would be thrown out of the combination and a salt result that would not be the one sought for.

To test its antiseptic properties, I performed the following experiments: (*a*) Animal infusion. (*b*) Vegetable infusion.

(*a*) Chopping into fine pieces some fresh beef that had been slaughtered two days previously, I placed an equal portion in two vessels and covered the same with two fluid-ounces of water. To one I added one grain of the sodium silico-fluoride. In eight days' time the plain infusion showed signs of putrefaction, and bacteria could be demonstrated in large numbers. The infusion containing the sodium silico-fluoride remained perfectly sweet and without odor for a period of three weeks, and at that time no bacteria could be demonstrated.

(*b*) I took some ordinary timothy hay, chopped it into small pieces, and boiled it with some distilled water in a flask for fifteen minutes. I then filtered it and set it aside, in two test-tubes, in a warm place. Into one I dropped one grain of the sodium silico-fluoride, which made a solution equivalent to one part sodium silico-fluoride in one thousand parts of water. In three days' time the plain liquid was swarming with bacilli. After allowing the other tube to stand for one month no sign of life or of putrefaction could be demonstrated.

To test the pharmacological action of sodium silico-fluoride the following experiments were performed:

1. Two rabbits of about equal size and weight were obtained. To one whose weight was thirty ounces, eight and one-half grains of sodium silico-fluoride, enclosed in a gelatin capsule, was given *via* the gastro-intestinal route; at ten minutes after 11 o'clock A.M., January 6, 1889. Both rabbits were allowed to run around the room so that their actions could be compared. Twenty minutes after the administration of the salt, the rabbit became quiet, lying at full length on the floor, showing no inclination to move. 11.35 A.M. Still lying full length, decidedly unwilling to be disturbed; respirations hurried and about 125 per minute; eye reflexes prompt; ear reflexes prompt; anterior skin reflexes prompt; posterior reflexes diminished. 11.40 A.M. Respirations still more hurried, 160 per minute; when aroused decidedly weak in posterior extremities. 11.50. Becoming restless; respirations about the same. 12 M. Seems to have regained its strength, running about as the other rabbit. 12. 40 P.M. Beginning again to show signs of weakness; hard to arouse. 12.50 P.M. Sensation posteriorly diminished. 1 P.M. Lying at full length; posterior reflexes entirely abolished; ear reflexes abolished; impossible to make rabbit move by poking. 1.10 P.M. Rabbit falls upon its side violently trembling; spasmodic contractions of the posterior extremities; respiration very slow. 1.12 P.M. Spasmodic contraction of anterior extremities. 1.13 P. M. General convulsions with collapse; all reflexes abolished; respiration hardly perceptible. 1.16 P.M. Respirations apparently cease; relaxation of all the muscles, with relaxation of vesical sphincter, and a voiding of a small quantity of urine; only sign of life was a slight trembling in the carotid region; pupils dilated. 1 20 P.M. Opened thorax; heart beating 80 per minute. 1.23 P.M. Opened thorax; heart beating 68 per minute. 1.26 P.M. Opened thorax; heart being 52 per minute. 1.30 P.M. Opened thorax; heart beating 40 per minute. 1.44 P.M. Opened thorax; heart beating 32 per minute. 1.50 P.M. Rigor mortis. 1.55 P.M. Heart beating 24 per minute. 2 P.M. Heart beating 10 per minute. 2.05 P.M. Heart beating 3 per minute. 2.06 P.M. Heart ceased beating.

Upon necroscopical examination the heart was found arrested in strong systole; the right auricle was full of blood, with no clotting; the ventricles were entirely bloodless, having been squeezed perfectly dry by the strong svstole; the lungs were found to be slightly injected and entirely collapsed; the stomach was greatly distended with food, although the rabbit had not been fed for twelve hours previous to the experiment; the mucous coat readily peeled off in large pieces, leaving the muscular tissue entirely bare; the large intestines were distended; the abdominal aorta was full of dark fluid blood; the kidneys were pale and bloodless; the bladder was empty.

2. Administered hypodermically into the posterior lymph spaces of a frog, fifteen minims of a 6 per cent. solution of sodium silico-fluoride at 8.30 P.M. This seemed to make little or no impression, excepting to hurry the respirations. At 10.15 P.M., again administered fifteen minims of the same solution; again had hurried respirations. 11.05 P.M. Showed motor paralysis of anterior extremities; pinching of anterior extremities caused contraction of the posterior extremities. Placed again upon its abdomen, it draws up its posterior extremities, but has no control of the anterior. The superficial veins in posterior extremities appear very much distended, the web show-

ing marked congestion; eye reflexes very sluggish. 11.40 P.M., showed marked paralysis of entire body; no movements perceptible except those of respiration. 11.57 P.M. Respirations very slow. 12.01 A.M. Respirations apparently cease. 2 A.M. Heart still beating.

3. In order to demonstrate if the salt had any action on the reflex functions of the spinal cord, the method of Türck was employed. Its principle consists in comparative measurements of the time required, before and after poisoning, for a given stimulus to the skin to evoke a reflex muscular contraction in a frog, from which the cerebral hemispheres have been removed. To accomplish this, a frog was taken, and an incision made through the occipito-atlantal membrane, thus exposing the medulla oblongata. This portion of the cord was divided, and the brain destroyed with a needle. After the spinal ganglia had regained their tone, indicated by the frog assuming the normal position, it was suspended by a hook passing through its nose. A test liquid was then made of a very weak aqueous solution of sulphuric acid. This solution was brought under the frog, just so the tip of his toes entered the liquid, and the length of time required before the frog withdrew its foot was determined by counting the beats of a metronome. As soon as the reflex movement occurred the frog was immersed in some fresh water, to remove the excess of acid and prevent corrosion of the skin. The metronome was set at sixty beats to the minute.

10.34 " No reflex action. Very hard pinching of posterior extremities caused reflex in the anterior extremities. No reflex action to actual flame.

4. A frog was taken, and after the femoral artery in the left leg was ligated thirty minims of a 6 per cent. solution were injected into the posterior lymph sacs at 9 P.M. 9.30 P.M. The recti abdominis were very stiff and hard, and gave no response to electrical stimuli. 9.15 P.M. Both posterior extremities respond to electrical stimuli. 9.21 P.M. Both respond. 9.26 P.M. Muscular trembling of right leg. 9.33 P.M. Stimulation of nerve equally prompt; reflex stimulation almost abolished in right posterior extremity.

5. 9.20 P.M. Immersed some fresh muscle in a 6 per cent. solution, and the blood coagulates at once. 9.21 P.M. Prompt response to electrical stimuli. 9.30 P.M. Prompt response to electrical stimuli. 9.50 P.M. No response to electrical stimuli. Muscle very hard and white.

6. Took a frog's heart, beating twenty-eight to the minute, and immersed it in a 6 per cent. solution. The first half minute the heart made ten beats, then stopped for one minute, after which it gradually diminished in force, stopping in systole.

7. Took some egg albumen and dropped it into a 6 per cent. solution of sodium silico-fluoride, and it immediately coagulated.

These experiments were repeated a sufficient number of times to guarantee the accuracy of the observations. Lack of laboratory facilities prevented the making of more extended pharmacological investigations. My attempt to determine the action of sodium silico-fluoride on blood pressure failed, for want of instruments to properly indicate the result of the administration of the drug. However, the foregoing experiments give us an idea of the general action of the drug, and indicate the probable paths of this action. Sodium silico-fluoride administered to either warm- or cold-blooded animals, as has been demonstrated, exhibits its action by marked stimulation of respiration. This stimulation passes gradually into paralysis of the respiratory function. Now, in case of paralysis, it is readily determined whether the case is peripheral or central. In experiment No. 4, it has been demonstrated that both muscle and nerve retain their power of transmitting the electrical stimuli. This at once excludes the probability of the drug acting through the terminal filaments of the respiratory nerves. Moreover, if convulsions are produced their nature also will give a clear geueral idea as to their origin. As convulsions of central origin throw the entire, muscles or entire groups of muscles, into coördinated contraction, so, on the other hand, convulsions originating in the nerves, or in the intra-muscular fibers, at different muscular fibres, at different times, and with different degrees of vigor, produce the so-called fibrillar contractions. The above experiments show that convulsions are a marked symptom of poisoning by sodium silico-fluoride, and also show that these convulsions are general, rather than fibrillar or local, thus indicating that the action of the poison is upon

the central rather than upon the peripheral nervous system.

These experiments also show that sodium silico-fluoride causes a condition closely allied to that known as rigor mortis, by an ultimate direct action on the muscular tissues. As the drug coagulates albumen even in weak solutions, quickly causing coagula to form in warm blood, it also probably coagulates myosin in the muscular tissues. These experiments also show that the automatic functions generally ascribed to the medulla oblongata, regulation of the heart, and vaso-motor tonus, and pupil mechanism are seriously disturbed. The venous system is greatly dilated, the heart beating after cessation of respiration, and the pupils are dilated at the moment of death.

In regard to reflex action, the experiments showing no loss of the power of coördination, that both the muscle and nerve retain their power of transmitting electrical stimuli, and, finally, that the spinal cord itself retains this power, we can conclude that the loss of reflex action after the administration of sodium silico-fluoride is probably due to paralysis of Setschenow's center. Finally, in regard to the action on the circulation, these experiments indicate that sodium silico-fluoride first increases the heart's action by stimulation of the vaso-motor centers, and finally lowers and destroys the heart's action by a direct influence on the heart's contained ganglia.

CLINICAL EXPERIMENTS WITH SODIUM SILICI-FLUORIDE IN THE CLINIC OF PROF. GOODMAN.

CASE I.—Ralph M., admitted to the hospital March 28, 1888. The patient was eight years old, born in Chester, Pa. The case presented the following interesting features: The anterior wall of the bladder was entirely wanting, and the posterior wall protruded like a hernia through a somewhat circular opening in the abdomen, just above the pubic arch. There was an absence of the umbilical cicatrix. The mucous surface exposed measured three-quarters of an inch, and was of a pale-red color, with brighter spots upon the surface. The right ureter was normal, the left appeared to be hypertrophied. The pubic bones were not entirely ossified, being fibrous for about an inch on each side of the symphysis pubis. There was only a very rudimentary penis, showing the partially formed urethra upon the dorsal surface. The scrotum was not developed. The testes appeared normal and were located under the skin on the inner side of each thigh. Their presence could be demonstrated by the cremaster reflex. There was also an oblique inguinal hernia of the right side. When admitted there was much excoriation of the surrounding parts, caused by the constant dribbling of the urine. These parts were washed frequently with a 1 to 1000 solution of the sodium silico-fluoride and the urine collected upon absorbent cotton. Various devices were suggested and tried to remedy the deformity. All these devices having failed, it was thought best to attempt the formation of an artificial bladder, by turning down a flap of skin, brought from the abdomen, and covering the same with flaps from the inguinal region. The patient being anæsthetised, an incision was carried from Poupart's ligament through the skin and superficial fascia, one and one-quarter inches from the median line to about nine inches up the abdomen on each side, and united at the top by a curved incision. The upper part was dissected down for four and one-half inches, being two and one-half inches in width. The edges of the flap were carefully stitched with catgut to the edges of the lower part, and the raw surface covered by flaps brought from the groin on either side. A drainage-tube was inserted into the newly formed bladder, a subsequent operation being necessary to form a urethra and modify the penis. In dissecting and handling the flaps, great care was exercised, and a solution of sodium silico-fluoride, one to one thousand, was constantly used during the operation. The patient was bandaged in a sitting posture with thighs well flexed. He rallied and the prospects were good for a recovery, but in about twenty-four hours suppression of the urine set in, and about thirty-six hours after this event he succumbed to uræmia. At the time of his death the wound was examined and it was found that primary union had taken place.

CASE II. *Amputation at lower third of Forearm, for Epithelioma of Dorsal Surface of Hand.*—Joseph L., aged fifty-three. He first noticed a small sore spot appear nine years previously, and did everything anybody told him, but the sore did not improve, and finally reached a large size, as shown by the accompanying photograph. He was admitted into the hospital, and the day previous to operation the arm was washed, shaved, and dressed with gauze wet with the sodium silico-fluoride, one to one thousand. The day following, the arm was amputated, making an antero-posterior flap with a circular of the muscles. The bones were at first sawn about half an inch longer than necessary, after which the periosteum was split and stripped from the bones. The bones were again sawn and the periosteum united with catgut ligature, and a small bundle of fine catgut was introduced for drainage. During the operation the arm was kept sprayed with a one to one thousand solution of sodium silico-fluoride. The arm was dressed with iodoform and the bandages were not removed for one week. At the end of that time complete union had taken place, and the patient was allowed to depart for his home the day following. Since that time the patient has been seen twice, and he reports that within one month after the operation he was in his fields ploughing with the lines hung over his stump.

CASE III.—In a case of gonorrhœa, which the patient claimed was his first attack, injections of sodium silico-fluoride, half a grain to the ounce of water, were used, and upon the fourth day of the treatment the patient showed no signs of any discharge.

In cases of conjunctivitis and conjunctivitis neonatorum, a one to one thousand solution works very nicely, affecting a cure in a few days.

Dr. Ziegler, resident physician at the Wills' Eye Hospital, reports that after cataract operations the continued use of sodium silico-fluoride did not answer very well, as in very nearly every case it set up a slight amount of conjunctivitis.

As a solution in which to keep instruments during an operation it does not answer very well, owing to the fact that the instruments are tarnished and spotted, no doubt from the effect of oxidation. This action can be diminished by adding sodium bicarbonate to the solution in quantities sufficient to render the solution strongly alkaline.

Since writing the foregoing, I have received a communication from Mr. William Thomson, of Manchester, and he was also kind enough to send me a sample of sodium silico-fluoride, which salt he has had registered under the name of salufer (probably from the two Latin words *salus* and *fero*, meaning safety bearer). Quoting from his letter received as above, he says: "In reply to your favor of the 24th ultimo, I don't know whether the preparation you have is perfectly satisfactory. The hydro-fluoric should be carefully combined with silica, and the resulting compound carefully neutralized with soda. If this is not done, the salt is liable to prove fatal to rabbits or guinea-pigs in large doses, much more so than if not so prepared. In human beings vomiting would be produced at once. A solution of salufer (sodium silico-fluoride), same as sample sent, does not coagulate albumen. It is probable that Rosengarten & Son's sample may not be prepared, as it is only possible to dissolve 2.68 grains of that salt in one ounce of water. The formula is Na_2SiF_6."

After a careful analysis, I found that the sample of salufer received from Mr. William Thomson contains 98.9 per cent. sodium silico-fluoride (Na_2SiF_6); 1.1 per cent. free silicic acid. It has an acid reaction to litmus paper. The aqueous solution coagulates egg albumen to a small extent, but not less than the American sodium silico-fluoride experimented with. In this attribute the two preparations are exactly alike. One part of salufer dissolves at 50°F. in one hundred and fifty parts of water, except the 1.1 per cent. of silicic acid, and in this attribute is similar to the American, the latter being, however, completely soluble and free from silicic acid.

Salufer contains 24.2 per cent. of sodium, Rosengarten & Son's sodium silico-fluoride contains 24.4 per cent., and Na_2SiF_6 contains, theoretically, 24.5 per cent.

The acid reaction in salufer is destroyed by the addition of carbonate of sodium in excess, as follows: Na_2SiF_6 $3Na_2SiO_3$ $3CO_2NaSiO_3$ 6NaFl, and in this reaction it acts precisely the same as the silico-fluoride of sodium of Messrs. Rosengarten & Sons.

No further chemical or physiological difference than the 1.1 per cent. of free silicic acid in the salufer was found in the two preparations, and this 1.1 per cent. is an impurity of no medical use.

We may sum up in conclusion that sodium silico-fluoride is:

1. An efficient antiseptic.

2. That a solution of one grain to an ounce of water is quite strong enough for ordinary purposes; in that strength being apparently unirritating.

3. That the solution is unirritating to the hands, which is no small advantage to those operators whose fingers are easily irritated by ordinary antiseptic solutions.

4. That a solution of one grain to the ounce may safely be used to syringe out closed cavities, even where the operator cannot be certain of all the fluid returning.

5. That it acts very efficiently as a deodorizer of the hands, after examining carcinoma of the uterus or rectum, by steeping the hands in a saturated solution. The odor is removed more efficiently than it is by any solution with which I am acquainted.

6. That a very convenient and comfortable antiseptic poultice may be made by soaking gauze or absorbent wool in a hot solution (ten grains to the pint), wringing it freely of excessive moisture, applying it to the wound and covering with gutta percha tissue.

Note taken from the British Medical Journal, May 19, 1889. Mr. A. W. Mays Robson, F.R.C.S., Honorary Surgeon Leeds General Infirmary, and Lecturer on Practical Surgery at the Yorkshire College:

"It is chiefly to find a safe and efficient antiseptic that I have, during the past few months, been using salufer almost exclusively in my surgical work. Before describing details of critical cases which incontestably try the value of any antiseptic, it might be well to mention a few of the uses to which I have put salufer, and unless otherwise stated, a solution of twenty grains to the pint of water is always understood, which proportion seems to be at the same time unirritating and efficiently antiseptic. They are as follows:

"In washing out the peritoneal cavity after laparotomy, here using ten grains to the pint; in the case of strangulated hernia; in the radical cure of hernia; in excision of joints; in amputations of the arm, leg, or thigh; in washing out the pleural cavity in the removal of tumors; in excision of veins; in ligation of bloodvessels in compound fractures; in osteotomies; in washing out the bladder; in washing out the uterus after curetting the interior; and after the removal of septic retained membranes; as a vaginal douche before and after Apostoli's operation for fibroid; in the irrigation of extensive ulceration in the rectum, where a poisonous antiseptic could not be used; in washing out the stomach; as an injection in gonorrhœa; in syringing out large pelvic abscesses; as a gargle in hospital and in diphtheritic sore throat; as a nasal douche after removing polypi; for syringing out empyema of antrum, and in many other cases."

"[1] Salufer (sodium silico-fluoride) appears to have a highly solvent effect on exposed dentine, and cannot be used as a devitalizer, being irritant and not caustic in its effects. In pulpless molars, where there is a mass of dentine to be removed, it can be safely used, if sealed in the cavity for two days before excavating. After extracting it assists in the arrest of bleeding, and used afterwards as a mouth wash has a hardening effect on the gums.

"After the removal of tartar and the sulphate of copper treatment for pyorrhœa alveolaris, a single daily application of the powder has kept the gums healthy."

REPORT ON CASES OF THE ALEXANDER OPERATION.

(Read before the Ohio State Medical Society, May 23, 1889.)

By D. TOD GILLIAM, M.D.,
Professor of Obstetrics and Diseases of Women, Starling Medical College, Columbus, Ohio.

IT is not the purpose of this paper to discuss the Alexander operation, either to advocate or deny it, nor yet to marshal an array of cases to swell the statistics, but simply and briefly to report a few cases, the chief interest of which lies in the fact that ultimate good followed in several such as were stamped as failures at the time of operation. I may here say, that in all cases operated on the ligaments were found, but in many there was a marked disparity in size and strength on opposite sides.

The operative failures were due to rupture of ligaments, either by inherent fragility or because of the inordinate force necessary to overcome the adhesions. In a certain proportion of cases the breaking of ligaments is not to be obviated, and, therefore, this is to be classed as one of the unavoidable accidents of the operation. Neither can the accident be foreseen nor guarded against, as it occurs in patients of every type of constitution and every phase of physical condition. This, it must be admitted, constitutes a serious drawback to the operation, and if (as in my own experience), several cases occur in succession, is calculated to discourage the operator. Should such a number of misfortunes attend the early efforts of an operator, it is easy to see how it might lead to the abandonment of the operation. Munde, than whom, probably, no man in this country has had a larger experience in this line, writes me that his experience coincides with mine in this particular, and while he deplores the unavoidable nature of the difficulty, reaffirms his faith in the operation as expressed in his writings.

It is hardly necessary at this day to describe the operation *in extenso*, but inasmuch as many of the text-books make no allusion to it, a brief description may not be amiss. As a preliminary, it is absolutely essential that all adhesions be broken up and the uterus be placed in the normal position. It is a good plan to hold it so during the operation by a well-adjusted pessary, especially in the absence of a trained assistant, as this obviates the necessity of introducing the fingers into the vagina during the act of operating. The patient being laid flat on the table, and the pubis shaved, the operator takes his position on the side opposite to that to be operated on. First, locate with the finger the spine of the pubis, and cut boldly down on it, extending the incision one and a half to two inches in the direction of the anterior superior spinous process of the ileum. In this way the external ring of the inguinal canal is reached, and a knuckle of fat protrudes. This being carefully divested of its investing membrane is seized with broad tissue forceps and lifted up, when it is grasped by the thumb and forefinger of the left hand. By spreading it over the end of the finger the ligament is recognized. It is now separated and drawn out, the redundant fat cleared away, the hemorrhage staunched, and the wound thoroughly cleansed by antiseptic irrigation. The ligament is now stretched to the pillars of the external ring, preferably by silkworm gut suture, the frayed ends cut off, and the remainder tucked away in the wound. A drainage-tube is introduced into the canal, extending outward along the bottom of the wound, and the latter is then closed by interrupted silk sutures. A fold of iodoform gauze, held in place by adhesive strips, completes the dressing. The patient is put to bed with the knees flexed. In all, these two precautions are always observed: First, to abstain from any act or manœuvre by which the knuckle of fat will be disturbed in its relations or pushed back into the canal, and, second, to preserve the moorings of the ligament at the pubic bone until it shall have been secured, drawn out, and made fast by suture to the pillars of the ring. I hereunto append a brief history of three cases, which, through rupture of the ligaments, were at the time classed as failures, but which unexpectedly gave gratifying results:

CASE I.—Catharine G., aged twenty-seven, married; has had two living children, the youngest being three years of age. Attributes her trouble to a miscarriage at seventh month five years ago. Complains of pain in the head, stomach, and back, and radiating pains extending down right side. Menstruation regular but painful. On examination, find retroversion of uterus and prolapsus of right ovary, the latter being somewhat enlarged and very tender; uterus adherent. The adhesions were broken up by the Schultze method, and the fundus brought forward to the abdominal walls. Operation, Saturday, January 12, 1889. The ligament of the right side was about the size of a chicken's quill, that of the left being not larger than a knitting needle. Both were quite firmly adherent, and required much tact in separating them, the left breaking in the act. An injudicious attempt to bring the uterus farther forward caused the right ligament to break also. In this case an erysipelatous inflammation ensued, with suppuration, extending between the muscular layers as far up as the hypochondriac region. An examination, made ten days after the operation, revealed the uterus in a normal position, which it continued to maintain up to the time of the discharge, which, owing to a tedious convalescence, was several months after. The patient improved greatly, and was sent home feeling quite herself again.

CASE II.—Mrs. Martha B., aged twenty-seven, has had two miscarriages; suffers from pelvic pains and dragging. Found uterus completely retroverted with adhesions. Adhesions broken up, under ether, by Schultze's method, Saturday, March 8, and uterus replaced. Monday, March 10, there being no reaction from Saturday's work, cut down first upon left ligament, which was found without much difficulty, and of fair size. Traction to overcome adhesions resulted in its breaking high up in the canal. The right ligament was now gone after and found to be very slender. Could not make it run, though it was brought out one and a half inches. The wounds were closed in the ordinary manner and the patient put to bed. Operation a failure. March 17, examination reveals uterus in normal position, and as it

never before remained so, even for a few hours, it is possible that the result may be better than anticipated. Six weeks later the uterus remained in its normal position, and the patient was discharged after adjusting an Albert Smith pessary.

CASE III.—Rebecca M., aged thirty-two. Four years ago fell on the ice, since which has been confined to bed most of the time. On examination, I found the uterus retroverted, which being replaced, and a pessary introduced, gave marked relief. Not wishing to be dependent on the pessary, she chose the more radical relief by the Alexander operation. Accordingly, on March 25, the operation was performed at St. Francis' Hospital. Both ligaments gave way after being drawn out about two inches. Suppuration ensued, and she was kept in bed about five weeks. Repeated examinations showed the uterus firmly in place, and any attempt at retroversion was accompanied by dragging and pain in the hypogastrium. Before being sent home a pessary was adjusted.

These patients have all passed from under observation, and with one exception, the last, I have been unable to communicate with any of them. I will not presume to say that the results are permanent, but, to say the least, they are striking and suggestive, and should lead to further investigation. Neither do I know how to explain the phenomena except on the ground of spastic contraction of the ligaments under the influence of peripheral irritation incident to operative interference. This, of course, presupposes that the ligaments have maintained adhesion or contracted new ones within the canal. We have analogous conditions in the spastic contractions of the extremities and in the condition of both cells, but more especially in the temporary contractions of the spermatic cord in urethritis, when the cord is shortened and the testicle drawn well up independently of the dartos. Should future observation prove these conditions lasting and their induction practicable, a suggestion for the use of electricity or other form of local irritation is clearly patent.

The Polyclinic.

COOPER HOSPITAL.

CONCUSSION OF THE SPINE.

IN structural changes in the spinal cord following injuries, whether the injury results from a fracture of the vertebræ, laceration of the spinal cord, hemorrhage into the spinal canal, or inflammation of the cord and its membranes, certain well-defined and easily recognized symptoms are developed. But that hyperæmia or anæmia of the cord may follow an injury, at an indefinite period, as a result of the shock of the injury, is questionable. Several years' experience as a railway surgeon has *not* shown me that such conditions exist independently of structural changes in the cord. In suits for damages against railway companies such conditions are generally built by experts from subjective symptoms.

Unlike the brain, the spinal cord is particularly protected against shock. It does not fill the canal in which it is contained. Its investing membrane does not form a periosteum to the bones, but is separated from the spinal column, and protected from it by areolar tissue and plexuses of veins. Neither does the membrane, like that of the brain, send partitions into the fissures of the cord. It loosely surrounds the cord, and is separated from the walls of the spinal canal, only sending from its sides prolongations to protect the spinal nerves in their exit through the intervertebral foramina.

If the conditions named above are brought about through the medium of the sympathetic nervous system, they must, if functional, be transitory; if organic, they must give rise to the well-known symptoms of structural disease of the cord.

The result of a suit for damages against a railway company for the condition known as a "railway spine" often produces a speedy cure.—*Godfrey.*

MEDICO-CHIRURGICAL HOSPITAL.

CASE OF ENTERECTOMY FOR STRANGULATED HERNIA.

Reported by John W. Croskey, M.D., Chief of Clinic.

JNO. BURNET, aged twenty-nine, American born. Was admitted to the Medico-Chirurgical Hospital, May 15, 1889, suffering from a tumor in the left inguinal region. He presented the following history: Five years ago he had an attack of gonorrhœa, about one year later he had a second attack which left him with a stricture of the urethra. This was cut by the late Prof. Gross about two years ago. Following this he had two more attacks of gonorrhœa and recently he was able to urinate only after the greatest straining, which would cause a spasm of the entire body. On Thursday, May 14, 1889, while following his vocation, that of a fish monger, he was seized with a desire to urinate. He got off of his wagon and after making an effort which failed, he was taken sick at his stomach, and while vomiting was seized with an intense pain in his groin, which prevented him from assuming the erect posture. He was taken home and a doctor was sent for, who diagnosed an indirect inguinal hernia. He was given ether and an effort was made to reduce it but with no result. It was then decided to send him to the hospital; and on Thursday, May 17, forty-eight hours after the occurrence, he was operated upon by Prof. H. Earnest Goodman with the assistance of Prof. Montgomery.

The operation consisted of an incision made over the tumor in the right inguinal region, by pinching up a fold of the integument and by one cut dividing the skin, after which the tissues were successively divided down to the peritoneum, this was then picked up with a pair of forceps and nicked, after which five inches of the bowel and about nine inches of the omentum were disclosed as being strangulated. Mortification had already begun, the intestines and omentum being quite black and softened. It was decided to resect the bowel, and after compressing both ends of the intestines five inches of the ilium were removed and nine inches of the omentum ligated and cut off. The two ends of the intestines were brought together

with the Czerny-Lembert suture. To make the union more secure some fine black silk sutures were passed through the peritoneal covering about one-quarter inch back from the inside line of sutures on each side and drawn together. The mesentery was united by the uninterrupted catgut suture. The parts were then washed with some silico-fluoride of sodium (1–1000) and afterwards with some hot water, when the parts were returned. The wound was united with silk-worm gut, leaving in a glass drainage tube. The wound was dressed with iodoform and cotton and a spica bandage of the groin was put on. After the operation the patient rallied nicely. To allay thirst injections of hot water were used and the patient was given nothing until the next day. The day following, May 18, the temperature was normal, pulse 100. Bovinine was ordered every two hours and warm injections every three hours.

May 19.—Morning temperature 103° F.; evening temperature 100.1; bowels moved twice.

May 20.—Morning temperature normal; evening temperature 100.2°.

May 21.—Morning temperature 99.3°; evening temperature 99.4°; one movement of bowels; drainage tube removed.

May 22.—Morning temperature 99.3°; evening temperature 98.2°; four movements of bowels.

May 23.—Morning temperature 99.3°; evening temperature 98°; one movement of bowels.

May 24—Morning temperature 100°; evening temperature 101°; one movement of bowels.

Cream and bicarbonate of soda added to the diet.

May 25.—Morning temperature normal; evening temperature 100.$\frac{2}{5}$°; one movement of bowels.

Cream toast and milk punch added to diet.

May 26.—Morning temperature 99.$\frac{8}{5}$°; evening temperature 99°; one movement of bowels.

May 27.—Morning temperature 99°; evening temperature 98°; one movement of bowels.

Meat juice added to diet, two grains of quinine three times daily.

May 28.—Morning temperature normal; evening temperature 98°; one movement of the bowels.

May 29.—Morning temperature 98.$\frac{3}{5}$°; evening temperature normal; two movements of bowels.

May 30.—Morning temperature normal; evening temperature 99.$\frac{3}{5}$°.

June 18.—Patient is up and doing well, functions appear perfectly normal.

POLYCLINIC NOTES.

Contributed by Dr. George M. Gould.

ENDO-AUSCULTATION.

A NEW method of physical examination has been devised by Bianchi, which consists in making use of the common œsophageal tube passed into the stomach to auscult the gullet and stomach, and through them the heart and lungs. The tube is bifurcated at the upper end and with ear-pieces, as in a binaural stethoscope, and the inventor says sounds may thereby be detected indicative of a smooth or rough condition of the mucous surfaces over which it travels, the presence of foreign bodies, diverticula, tumors, etc. From the weakness or absence of the cardiac and respiratory sounds conclusions may be drawn as to the thoracic organs, the walls of the stomach, etc.

THE RELATION OF MALARIAL AND TYPHOID FEVERS TO PHTHISIS.

In the last most admirable report of Dr. Seaverus, the Medical Examiner-in-chief of the Royal Arcanum, he finds that the records of the order seem to show an exceptional tendency to the development of phthisis in those who have previously had typhoid or malarial fever. No definite statistics are offered, but the suggestive question is asked if there be such a causal relation, or if examiners do not disregard incipient consumption under the mistake that it is only a simple malarial affection?

DEATHS IN LONDON STREETS.

In 1869, the number of deaths from accidents in the streets of London was 192, and in 1888, 237. This is an increase of 23 per cent. It is of interest to note that during this time the population increased 34 per cent., and that the deaths increased from 1869 to 1882, when the number was 271, decreasing steadily since despite the increase of population.

DISEASE OF THE NIPPLE.

Dr. Darier claims to have proved that Paget's disease of the nipple is of parasitic origin, and suggests that this discovery may be the first step towards the elucidation of the nature and mode of origin of some epitheliomata.

POST-MORTEM SWEATING.

Cones (*Lancet*) cites a case believed to be unique, in which a large amount of sweat was poured out after death. Pilocarpin injections had been given before death, but not later than three days prior to death. The sweating was first noticed some sixteen hours after death, and continued profuse for eight hours thereafter.

ARTERIAL MURMURS.

Dr. Phillips (*Lancet*) thus summarizes his conclusions upon this subject:

1. A murmur is sometimes audible in the subclavian artery immediately below the clavicle, which is not the result of organic disease or of pressure upon the artery, and is most common in anæmia and other conditions where there is defective adaptation of the arterial wall to the blood-current. 2. The various circumstances influencing the production and rhythm of the subclavian murmur are dependent upon its anatomical position and the respiratory movements. 3. Murmurs may be often heard in anæmia in the large branches of the aorta within the chest. 4. The respiratory movements have a marked influence on the character of anæmic murmurs in arteries arising within the thorax. 5. The murmurs heard in the subclavian and pulmonary regions in some cases of phthisis, inasmuch as they may exist without phthisis, must not be regarded as diagnostic of that disease, and are not produced by pressure of consolidated lung, in most of the cases where they co-exist with phthisis. 6. Murmurs may be originated in intra-thoracic arteries from traction upon them by the displacement of the heart in pleuritic effusion.

London Letter.

NEUROLOGY IN ENGLAND.

By L. HARRISON METTLER, AM., M.D.,
Lecturer on Mental and Nervous Diseases and Electro-therapeutics in the Medico-Chirurgical College of Philadelphia.

IF there be anything in the disposition of a Briton for which he is more famous than anything else it is his *sang froid* and abundance of nerve. It was that which made him stand firm before the avalanche of steel at Waterloo, and gave him the victory over the barbarous hordes of the scorching Soudan. Paradoxical as it sounds, nervousness really means a lack of nerve; and yet it is equally true of all the other organs of the body, that the less their owner knows subjectively about them, so much are they in the better state of health. Individuals and nations of a neurotic type are not so because they are more abundantly supplied with a nervous system, but because that nervous system has less of the *power of resistance*, which in its integrity is one of the prime requisites of health. To *act* and to *resist* are the special functions of nervous matter, and when one or the other predominates as the result of climatic and hereditary influences in the races and of degenerative and inflammatory diseases in the individual, we have an abnormal neurotic manifestation. In regard to race-types it is an extremely difficult matter to draw any precise lines; but if equilibrium, as manifested by the amount and quality of work done, with the minimum of suffering and decay, be the measure of popular health, then one must *à priori* award the palm, in regard to nervous health, at least, to the English speaking races. And so the facts prove; for with these races there are, comparatively speaking, less of the so-called *functional* diseases, when counted side by side with the *organic*, than there are in others. The Latin nations, for instance, being of a decidedly neurotic type, offer the most splendid opportunities for the study of the functional diseases; on the other hand, the Saxon races, being of a less neurotic type, present the best and most numerous examples of the organic variety.

Hence, neurology in England is of a more practical character; has, if I may be permitted the expression, more of a mechanical ring about it than it has in France or Germany. And this is also shown by some of the more prominent views held by English physicians in regard to many of the debatable functional diseases. Doubtless the rheumatic origin of the choreas is so strenuously urged by the London men because of their dislike to believe in any abstract reasonings about *balance of function*, etc., and because their experience with chorea of organic origin is the more extensive. Note, in regard to the epilepsies, how many of the views here are based upon its organic origin, and, doubtless, because here the type of the race causes a preponderance of the really organic epilepsies over those of the non-organic type about which the French authors write so much. The belief of Dr. Ranney, which he has acquired from experience, that nearly all epilepsies are dependent upon eye-strain, would find much quicker favor among these English physicians than among the French or German. In regard to the *localizations*, both of the cerebral areas and spinal tracts, one can clearly distinguish the practical, almost mechanical, line of thought common to the English race. The unitarian views of Goltz in regard to the workings of the brain and the close intercommunication of the various transmissions, so strenuously urged by Brown-Sèquard, do not please so well the Anglo-Saxon intellect as the more bald statements of Turner, with regard to the marked limitation of the cerebral areas, making the brain, with its various hemispheres and lobes, truly a *composite* organ.

And yet, though not psychologically inclined, Great Britain has done wonders towards advancing our knowledge of the nervous system, as all the world knows, and as I have had the opportunity to witness, after some weeks sojourn in Scotland and England.

But, after all, neurology, as a distinct science, may be said to be confined to London, for outside of this great metropolis there is not within the whole United Kingdom a single large hospital solely devoted to this specialty. But though The Nation of London, as De Quincey so aptly calls it, is quite adequate to supply material for the study of all phases of neurotic diseases, it is not dependent upon its own resources, for the hospitals, and one in particular, of which I will speak shortly (because of its superior appointments), receive cases from all the provinces, and not a few from other parts of the world.

This scarcity of hospitals for the special treatment of nervous diseases is not a little singular, when it is remembered how cold a welcome these unfortunate patients receive at the general hospitals, firstly, because of the long time their treatment usually requires, and, secondly, because of the extreme attention which must be given to most of them, two things which a busy general hospital finds itself unable to afford. Specialism is, undoubtedly, the evil of the day, and yet if one would want a conclusive argument in favor of the better results obtained by the specialists in neurology, he has but to watch for a time the workings of such hospitals as the Orthopædic and Infirmary of our own city, and the National Hospital for the Paralyzed and Epileptic of London. The latter is a richly endowed institution, and had we the time and space we could write a paper itself on the artistic beauty of its building and the systematic regularity of its regime, all being for the best interests and comfort of the inmates. When I mention that on its staff we find such men as Radcliffe, Hughlings-Jackson, Bastian, Gowers, Ferrier, Adams, and Horsley, the reader will understand why I have selected this Hospital for the expose of British neurology. And here I must express my indebtedness to several of these gentlemen for the courtesy which they extended to me while in London.

Sir Crichton Browne says: "True, just two diseases stand prominent in the title of the Hospital, but each covers a whole multitude of maladies. We have epileptics ranging from such 'weird seizures' as the laureate has described up to convulsive explosions, sudden and terrible, as if the brain were made of dynamite. . . . And we have paralysis rang-

ing from weakness in a finger up to death-in-life of the whole body."

Furthermore, a special hospital that averages five hundred cases a year will, of necessity, present all phases of its special diseases, though here, as elsewhere, most of the cases may be grouped under one of the two classifications of *degenerations* and *inflammations*. Degenerated tissues, of course, cannot be replaced, but under special and usually prolonged care the progressive destruction may be checked and the patient permitted to pass the rest of his life with what powers he has still left to him. And in so delicately organized a structure as the nervous system an inflammation needs more, both of time and attention, for its cure than can usually be given in a general hospital. As is well known, a large amount of surgery is associated with neurology, and this hospital has a large service of this sort as well.

As soon as one enters the building he is impressed with its artistic beauty, for the vestibule, large and airy and into which open the various corridors, is floored with marble mosaic, has its walls decorated with attractive colors, brightened by the bright rays of the sun streaming in through the stained windows, and its ceiling supported by beautiful Parisian columns. This first agreeable impression is not lost in passing on through the rest of the hospital, for the rooms and wards are all as bright and cheerful as they can be made. These are not trifles that we are dwelling upon, for I soon learned that in their treatment the London neurologists laid unusual stress upon the environments of their patients, insisting that they should always be of a bright and sunny character, and thus many a hopeless melancholia and obstinate hysteria has been made to disappear when the patient was removed from the wretched surroundings of his own poor hovel to the homelike rooms of the hospital. It is found that epileptics escape many of their usual attacks as long as they are kept engaged at something; so in some of the wards these poor sufferers, happier now than they were formerly, are seen sewing and constructing various articles, and are encouraged to various sorts of mental and muscular amusements. Watching them at their meals one will note how systematically they are drilled to follow the nurse at the head of the table. This is done to keep their attention from themselves as much as possible; at any rate it certainly favors the treatment that may be in the course of application by keeping off many attacks.

In the out-patient's room are comfortable benches for 200 or more persons. At one end of the room a certain Samaritan Society has arranged a refreshment counter, where a cup of tea or coffee with a piece of bread and butter is supplied for a penny. What a boon this would be to some of the patients of one of our hospitals, who are kept waiting for hours hungry and tired!

The wards, distempered in French grey and surrounded by large windows, admitting plenty of sunlight and capable of affording ventilation without draughts, consist of two apartments, a day room and a dormitory. Each ward has its own kitchen, bathroom, and offices. From twelve to eighteen occupants fill a ward. There are also smaller wards and private rooms for those who can and are able to pay for the privilege.

Electricity receives considerable attention here, both for its medicinal properties and aid in making diagnosis. About one-sixth of the whole number of patients undergo some form of electrical treatment. Though the electrical room contains a formidable array of apparatuses, galvanic, static, and faradic, the principal one used is quite unobtrusive, being only a table supporting a few insulated wires connected with a resistance coil and a galvanometer. The electricity is generated by a dynamo run by steam in a room below.

Most of the cooking is done by steam and gas, thus saving labor and preserving cleanliness. Steam is the mode of heating the rooms. There were many other details that I noticed about this comparatively new though well-known hospital, but I have only mentioned some of the more particular ones to show the practical determination of the London neurologist to try and secure for the long neglected class of nervous affections a better history of cures. And they are doing it, with some of the most obstinate cases. Excisions for neuralgia, suspensions for ataxia, trephining for traumatic epilepsies, electrical treatment for aphasics and paralytics, have afforded a notable percentage of happy results. Even the dreaded operations upon the brain and cord, usually so fatal, have here met with decided success. But in addition to all this, the wonderful strides taken in our knowledge of the nervous system and its disorders, with the advantages of comparison afforded by such a hospital as this must necessarily be of the greatest advantage to the outside general practitioner. Whatever may be one individual's opinion about the extreme views of some of the more advanced neurologists we must admit that they have opened up for us new methods of investigation and new facts.

As examples of the kind of work done at the National Hospital for the Paralyzed and Epileptic I may cite such cases as:

A girl of seventeen years of age, who had completely lost the use of both legs and one arm when she entered. The other arm was weak and there was loss of sensation in the lower part of the body and legs. Exhaustion and bed-sores had brought her almost to a dying condition. It took fifteen months to give her a perfectly healthy look and to restore the full use of both her arms. The power to walk had not yet been fully attained, though it had been wonderfully improved.

A hemiplegic, aged forty-one, who had been ill some fifteen months, with fits once a week and oftener, remained in the hospital about four months. There was a marked diminution in the number of fits, and nearly a complete restoration in regard to the hemiplegia when he left.

Obstinate neuralgias are usually treated by excision with the happiest results. In one case of a cranial nerve neuralgia of twenty years standing, the excision has so far given complete relief.

It is a medical treat to watch Mr. Victor Horsley in one of his private operations. The bright and

well-ventilated room, with its cases so clean and orderly, the extreme tidiness and ready attention of the "sisters" in waiting, the instruments on the table all so bright, of such large variety and so completely immersed in the antiseptic solution, the particular care to avoid any spattering of blood, all indicate the careful surgeon who recognizes the fact that success in his department is dependent upon attention to details. The spray is employed, and for the anæsthetic, chloroform. We were charmed with the perfect coolness and ready knowledge which this operator displayed in one of his excisions of the infra-orbital nerve, trephining the antrum and severing the nerve immediately after its emergence from the cranial cavity. A little electric light fastened by a strap to the forehead and furnished with a condensing lens enabled him to completely illuminate the antrum. The bromides are the mainstay here in the medical treatment of epilepsy. The general regimen and eye-defects always receive special attention in this affection, and as we have intimated before, there is something novel in giving special occupations and regular drills to epileptics. But the results seem to favor the adjuvants to the regular treatment.

An interesting case was that of a lad, seventeen years of age. He had had fits for three years, sometimes seven or eight a day. The third day after his admission he had two severe and two slight fits. During the next fourteen days he had only two slight ones. During the succeeding eighty-seven days no fits, and he was finally discharged cured.

A woman, twenty-nine years of age, had been subject to epileptic fits for ten years. The severe fits occurred every two or three weeks; slight ones, many every day. After her admission to the hospital she had no severe fits. During the first month they were slight, ranging from six to fifty a day. She remained in the hospital three months, during the last of which she only had five of the "petit" variety altogether, and so on. Of course, failures in the cure or even relief of these intractable nervous affections occur here as elsewhere, but the percentage of cures balances by far in favor of the special treatment of these diseases as it is afforded in the special hospital.

Not only in this treatment do we see the practical, almost mechanical, turn of mind of the British neurologists, but even in the forming of their diagnosis as well. Unlike the Germans, who revel in their abstruse reasonings, or the French who pore over their tomes of accumulated cases and inexhaustible varieties of nervous diseases, the English physicians only care for theories and classifications so far as they enable them to comprehend the nature of the trouble for its more complete and radical cure. Anyone can see this for himself by a glance through Gowers' work on "Nervous Diseases," which is an admirable portrayal of the author's method in the hospital: exact, minute, and looking always to the appropriate and available treatment.

Dr. Ferrier told me that he had now employed many times Charcot's suspension treatment in ataxia with always more or less favorable results. Of course, the question as to the permanency of the relief is still *sub judice*.

A large proportion of the out-patients which I saw at this hospital were cases of ataxia of specific origin, to whom the iodides were administered as usual.

In a remarkable case of ataxic aphasia, the frequently extreme emotional character of these patients was shown by the man crying out like an infant almost every time he was spoken to and attempted to answer. Nothing outside of general treatment was instituted in this case, as it was to be admitted to the wards later on.

Another out-patient illustrated in a marvelously clear manner how often tapping of the head and the corresponding sensation of pain, will localize a lesion. When tapped with the finger over a small area in the region of the occiput, the lad suffered such pain as to grasp the hand of the physician, while over the rest of the head he could be struck quite vigorously without feeling pain. The real interesting point of the case, however, was in showing how closely the other and more distant symptoms of localization tallied with this simple one. There was doubtless a certain amount of circumscribed meningitis along with the tumor in this case, and in all probability it was the meningitis that caused the pain.

Such are a few of the class of cases met with in the routine work of one of the largest and most elegant of the London hospitals, and while I could relate more, and even these in greater detail, I fear that the reader is already weary, and particularly if he be one of those who bear a little opposition to the "specialties." For his benefit then I will end by quoting what a certain doctor once said in answer to an inquiring layman about the special hospitals. "Why one would think it needed as many hands to cure a patient as it takes, we are told, to turn out a pin. Stuff and nonsense, sir! This minute subdivision of medicine and surgery into a multitude of specialties is ruinous to the best work, and both science and patients suffer when the physician or surgeon sees nothing beyond the limited field of vision upon which his whole professional attention is riveted. At the same time the area of knowledge is so vast now and the problems of our later day life are become so complex, that no man's sight can penetrate everywhere alike, and there are, and it is well there should be, specialists of the right type—that is, whose specialism is not the root and branch of their knowledge, but its blossom and fruit." If I wanted to be dogmatic I should say that special hospitals are only wanted for maladies not readily treated in general hospitals, and that the only right kind of special hospitals for treating such maladies are those which possess the services of men who can bring to bear the microscopic powers of a single eye when it is necessary so to adjust it, but are equally capable of using both eyes and can sweep the whole landscape. Our own sentiments precisely.

LONDON, May, 1889.

THE children of Dr. William T. Lusk, of New York, have benefited by the death of Mr. Chittenden, the Brooklyn millionaire, to the extent of nearly one million dollars each. Dr. Lusk has his summer residence at Newport.

THE AMERICAN MEDICAL ASSOCIATION.

THE meeting at Newport differed widely from its immediate predecessors. There was a small attendance; not over seven hundred and fifty registering at the outside. This was due to several causes combining. The Old Colony Railroad refused to make special rates, and the other roads consequently withdrew their offers to do so. Then, at the last moment, the Old Colony announced the reduction, when it was too late to take advantage of it, or to get the other roads to do likewise. The road ought to be boycotted by every friend of the Association.

The second element determining the small attendance was the absence of anything like a fight. We are very scientific, especially in the East, but we still take interest in a struggle for superiority.

Finally, the town of Newport presents no attractions to the physician, such as are to be found in the great medical centers—colleges, hospitals, clinics, and the great teachers of the day. In all respects our predictions in regard to Newport were fulfilled. The one hotel was crowded to repletion; so that many were unable to obtain even one of the antediluvian beds which almost completely filled up the cells in which we were to spend the nights. The cooking department broke down: so that guests were compelled to wait in front of the dining-room door for over an hour after the Sections opened their meetings before they could be served. For this, Newport could hardly be blamed, as she never made any pretense of being a city of hotels. It is to be hoped that things will be better in Nashville next year.

The Address of President Dawson dealt with medical education, medical literature, and the achievements of modern surgery. He discussed at some length the question of legislation upon medical matters, and opposed the creation of Examining Boards composed in part of irregulars.

The Address in Surgery was a feature of the meeting. Dr. Conner had certainly an abundance of material in the surgical work of the present generation, and he used it judiciously. He protested against the extravagant hopes which see in failure only an evidence of neglect on the surgeon's part, and recommended a collective investigation upon the subject of carcinoma.

The Address in Medicine was a disappointment. Those who had heard the brilliant clinical teacher of the University of Pennsylvania, looked for something in this Address which would in itself repay them for the journey and the inconveniences of the sojourn at Newport. Instead of this, they heard a stale biography of Rush. Dr. Rush was a very worthy gentleman, and we sincerely hope Dr. Gihon will succeed in raising a monument to his memory; but that is no reason why he should be foisted upon an audience which had collected from all parts of the country to hear Dr. William Pepper's views upon modern medicine.

In the selection of Dr. E. M. Moore, of Rochester, as the next President, the Association honored itself and testified its appreciation of his work, his services to the profession, and his devotion to the welfare of of the Association. We have been credibly informed that the candidate put forward in opposition to Dr. Moore failed to get a single vote outside of his own State; but whether this arose from the popularity of the one or the dislike of the other we are unable to say. The direction of the Journal is left in the same capable hands as during the past few months; the trustees being strengthened by the addition of Drs. Hooper, Garcelon, Love and Dawson. If the only question in this connection were the efficient management of the publication, there would be little to object to in this arrangement. But as long as there is no ostensible head to the Journal there will be intriguing and wire-pulling by persons who desire the post of managing editor. Some of these parties will do all in their power to embarrass the present management in order that their own selfish interests may be subserved. Factions will endeavor to thrust into the seat men who have been their tools in times past. These annoyances would have been prevented by the selection of a strong man to fill the chair. One cannot but admire the effrontery with which some of these men urge their alleged claims. Editors who have been persistent enemies to the Association, or who have been the most egregious failures in every sense, consider themselves fit to fill N. S. Davis' shoes!

The social features were not so elaborate as on former occasions. By far the most enjoyable was the excursion of the Medical Editors' Association, which was in all respects a success, and will long be remembered by the participants. But one unpleasant incident marred the harmony of the occasion. By some mischance, the last toast was assigned to a person who represented a pharmaceutical journal's advertising interests; and this man had so little conception of the amenities of civilized life that he em-

braced this opportunity, at a social gathering, to make a bitter attack upon an enterprise recently launched by one of the guests present, for which he freely predicted bankruptcy. The address was heard with surprise, which would have assumed the form of active indignation, were it not that the insinuations were couched in such obscure terms that few understood what the speaker was driving at. It is to be hoped that in future pharmacy will be somewhat more worthily represented. As the *Druggists' Circular* is in no way affected by the success or failure of the scheme referred to, it is evident that its advertising agent was simply put forward by some parties whose interests are more directly influenced; and who chose as their representative a man who was the only one connected with a pharmaceutical journal who could be induced to do their dirty work. That this was done with the deliberate intention of doing an injury to the project in question is shown by the fact that several slips containing the remarks in question were printed and mailed to the medical journals on the Saturday following. It is evident that somebody is pretty badly scared at the favor with which the consolidation journal has been received.

The clam-bake tendered to the Association by the Rhode Island Medical Society was a very elaborate affair, and was enjoyed by the guests.

Annotations.

AURAL EXAMINATIONS FOR RAILWAY EMPLOYES.

IN occupations that have to do with human life it is of the utmost importance that every possible safeguard be erected for the protection of life.

There is no other occupation in the country of such magnitude and danger, or with which the whole population is so intimately concerned, as that of railroading. Even though a man may never ride in a railway coach, he can hardly go a few miles from his home without having to cross a railroad track. And every day thousands upon thousands trust their bodies and their lives to the carefulness and abilities of a comparatively few of their fellow beings.

Railroad employés, then, having in their charge such valuable freight, should be picked men, whose common senses are as nearly perfect as possible.

Since the discovery of color blindness the cause of many former railroad accidents has been found out, and that menace to human life has now, in great measure, been removed. But there is danger through another sense, heretofore little spoken of—that of hearing.

At the late meeting of the National Association of Railway Surgeons of America, held at St. Louis, Dr. Robert Barclay read an interesting paper bearing on this subject, and holding that all those who apply for railway positions where hearing is of any moment, should be carefully examined by an aural surgeon, and that those also who are in service should be periodically examined, in order to discover if their hearing is degenerating.

These views we heartily endorse, and trust that railroad employers will give the matter the attention it deserves.

QUACK ADVERTISEMENTS.

QUACK advertisements must be found as frequently in the religious press of England as they are here, for the *Hospital Gazette* lately contained a strong condemnatory article on this subject.

When physicians write or speak against the evils of this practice there are none more ready to charge them with interested motives than the religious press. But these very papers, which ought to be as nearly as possible patterns of purity, advertise patent medicines for which the most absurd and unreasonable claims are put forth, such as consumption cures, cancer, and tumor cures, and the like. One may notice that a reverend gentleman, whose present address is some Bible house, while acting as a foreign missionary, had his attention called to a combination that is a specific for "nervousness, weakness, the indiscretions of youth," etc.; and although he is no longer a missionary, his philanthropic spirit is just as large as ever, so he will send this recipe, securely sealed, free. Cures for the opium habit are advertised, that have been proven by competent chemists to contain opium; cures for the slave to drink, that are known to contain alcohol. But it is needless to particularize; these abominations every medical man knows.

The columns in nine religious papers were examined a few days since, with the result of finding seventy-three quack advertisements. One of these papers contained as many as eighteen; but another, again, had only one. A religious newspaper with eighteen advertisements representing consumption cures, asthma cures, rupture, skin disease, blood disease cures, kidney and liver disease cures, opium and alcohol cures, does not impress us as exhibiting a high state of either intellectual, moral, or religious culture in its proprietors or its readers.

Letters to the Editor.

A SAMPLE.

I HAVE this to say—viewing the combination or "trust" from a busy practitioner's standpoint—the union of the two journals has detracted nothing from the value of either. On the contrary both are improved in the one.

THE TIMES AND REGISTER stands, to-day, the best medical weekly published for the busy general practitioner, and equals in every respect any of the five-dollar weeklies.

While I am a free trade democrat, and opposed to "trusts" generally, I verily wish there were more of the sort represented by the blending of such agencies for the propagation of elevated medical thought.

Wishing your enterprise much success.

SHARON GA. ARTHUR C. DAVISON.

POSITIVISM IN MEDICINE.

ALL the physical sciences are positive sciences with the exception of medicine. It is a complex science, and some of its parts are positive enough. Its general anatomy, physiology and chemistry are, as far as they have been developed, decidedly positive. Histology and pathology will go on enlarging as long as the microscope will be susceptible of improvement. But take its ætiology: what fluctuations does it not experience? what circles is it not made to travel? At one time it attributes disease to contagium; at another to infection; at one time to an organic morbific germ; at another to a chemical alkaloid, and at another still to molecular disturbance. The germ theory has run riot. Yet, notwithstanding its popularity, the theory of molecular disturbance, as causative of inflammatory processes, is more rational than that of an organic germ. Accepting, as we do, the doctrine of the cellular structure of all organized bodies, and the constant activity of those constituent cells, it is conceivable that that activity might become so disturbed as to amount to any degree of abnormality.

The "schoolmen" of the middle ages used to dispute as to how many angels could stand upon the point of a needle, and now physicians are speculating as to how many morbific germs can occupy a microscopic point of the human body.

This germ theory has been over-done, and sooner or later will experience a reaction that will establish its proper pathological position. According to its tenets now, the soil, water and atmosphere are but the abodes of infection and death. Suppose two germs should individually, but simultaneously, invade an organism and set up distinct morbid processes therein, say of scarlet fever and diphtheria, who has the positive diagnostic skill to decide that fact, and where and how would we draw the line of demarcation? Why does the physician, in his daily rounds, see in the same neighborhood, and perhaps in the same family, one case of typhoid fever, another of pneumonia, another of diphtheria, and so on, and all having about the same environments? The germ theory alone will not explain the phenomena. There must be some internal, idiosyncratic condition that particularizes each case, but a positive understanding thereof is yet to be evolved. Why does the same exciting circumstance set up in one case mere simple ulcerations, in another benign growths, and in another cancer?

There is no rule of reasoning yet known that can give a demonstrable solution to that extraordinary differential pathogenesis. The argument of heredity will not alone answer. There was a time, however remote, when the ancestors of the present generation of cancer subjects did not have cancer. We can only accept the philosophy of agnosticism and say: "we do not know."

Yet, notwithstanding that this subject of primo-pathogenesis is as yet impenetrable, the recognition of disease when once upon us, has been reduced to a positive science—diagnosis. With the present facilities for physical investigation; with a full armamentarium of examining instruments; with the urinary tests; with auscultation and percussion, a fatal error in diagnosis is inexcusable. The negative process of diagnostication—reasoning by exclusion—often confirms the positive one. In no department of science is positive reasoning more demonstrable than in disturbance in the cerebral function. With a solid bony structure between the seat of disturbance and the physician, he can yet trepan the exact spot. That is an achievement of the intellect alone and marks the positive possibilities of anatomico-physiological science.

The most deplorable circumstance in medicine is the evanescence of the systems of treatment. In it there is no permanence, no stability. Scarcely is one method accepted till another displaces it. New agents, whose active principles are unknown, and whose physiological action has never been tested, are constantly substituted for known and tried ones. Take, for instance, the antipyretics—and they are as the leaves of the forest in number. Physicians go wild over every new one that is announced, as if lowering temperature were curing disease. Take, if you please, typhoid fever, with the germ theory of its causation, and antipyretics can only modify the combustion; and modifying the combustion is only prolonging the stay of the intruder. If the so-called antipyretics at all benefit infectious diseases they do so by virtue of their germicidal properties. The cardiac inhibitors, such as aconite, invaluable in sthenic inflammations, are now largely displaced in country practice by mere heat reducers. They are given empirically, irrespective of their action in heat production, heat distribution, or heat radiation. Just contemplate the late craze on intestinal insufflation of gases in pulmonary tuberculosis. It was not only offensive to the senses, but disgusting to the understanding. Again, look at blood-letting, a most positive adjuvant in the treatment of inflammatory conditions in plethoric subjects. It has passed into almost entire desuetude in favor of the expectant plan of treatment, but more properly called the negative plan. All the mechanical ingenuity of the mind is strained in devising instruments, and all nature is searched for curative agents, but whether the science of medicine, as a unit, will ever be reduced to a positive science remains for yet distant ages to see.

U. M. SNYDER, M.D.

DELMONT, PA.

HOW CHLOROFORM REDUCES TEMPERATURE.

IN Dr. H. Culbertson's interesting article, in a recent issue of the TIMES AND REGISTER, p. 149, I find the following:

"When after death, in a chloroformed subject, the skin is cut, its substance is pale and bloodless. I have never lost a patient from chloroform, but under the profound influence of this agent I have seen the human patient pale and cold. Why is this? Is it not due in part to the nerve of Cyon and Ludwig being paralyzed?"

It appears highly probable that this question ought to be answered in the negative. I gather from the "Physiological Lectures" of Prof. Kuss, of Stras-

burg (Duval, Amory, Amer. Ed. p. 168), that the nerve referred to has no direct influence on the heart at all, and only influences it indirectly through the peripheral circulation.

How chloroform, ether, chloral, alcohol, and agents of this series, lower temperature, will be understood by a perusal of Dr. Lyman's "Anæsthetics" (Wood's Library). It is there stated that this effect is due to a retardation of the process of oxidation normally taking place in the body, on which the generation of its heat depends. The lowering of the temperature in poisoning by chloral hydrate and by alcohol, is so marked that in attempting to recover the victim of these states, the application of artificial heat is a prime consideration.

The same diminution, or arrest, of oxidation, which lowers the temperature, causes also a loss of muscular contractile power; muscle force being the direct product of the oxidation taking place within the muscle. Hence, the relaxation or flaccidity found among the complete effects of the anæsthetic agents mentioned above.

I would like, in this connection, to invite the attention of the readers of the TIMES AND REGISTER to a paper, read by me before the Physiological Section of the Ninth International Congress, at Washington, in which this and cognate subjects are discussed at considerable length. The paper is, On the Necessity for a Modification of Certain Physiological Doctrines, etc.

Dr. Culbertson, in appealing to the modern inhibitory hypothesis, in elucidation of the phenomena to which he refers, appears to have overlooked the fact, that this hypothesis, has, of late, been seriously discredited, and an attempt even made to set it aside and supersede it, by no less an authority than Dr. Lauder Brunton, whose admirable "Pharmacology and Therapeutics" will amply repay perusal.

If the editor will kindly permit me, I may offer him, soon, a criticism on both the inhibitory hypothesis, and the new one of Nervous Interference, which has been suggested in its place.

THOMAS W. POOLE, M.D.

LINDSAY, ONT., CAN.

The Inquirer.

A CASE FOR DIAGNOSIS.

A LITTLE GIRL, aged about six, of healthy parents, was remarkably healthy until, say, six months ago, when she was suddenly taken with "cramps" in her bowels; since when the same attacks have returned at intervals of a week or less; cramps extending to the legs, so that she is unable to stand or walk; is taken suddenly *at play*, and falls all drawn up; cries out for her mother to rub her, but sometimes she is so sensitive over the whole skin that she cannot bear to be touched. Appetite good, no indication of worms, has been treated for worms; bowels regular, no pain at stool, urination free and easy, no trouble in passing water, no indication of stone, no tenderness over bowels or bladder, no tenderness along spine, no indication of hip disease. She is a stout, well made, well developed little girl.

This is all I can say of her case. I give you the negative eliminations; there is nothing positive that I can see. She is evidently a great sufferer.

V. S. M.

[The given history of this case is that of recurrent spasms confined to the lower extremities, with intervals in which no aberration from health can be found. The indication is consequently directed towards a reflex cause, acting intermittently, and probably originating below the diaphragm. The search for this cause should be first directed to the bowels; then the kidneys and bladder. This has apparently been done by our correspondent. Then the genital organs should be examined for evidences of ascarides, or of masturbation. In such cases it is well, if an ordinary examination fails to reveal the cause of the symptoms, to strip the child to the skin and go over the body with the utmost care; scanning every outline and examining every organ. There may be a curvature of the spine, or commencing caries. Should such an examination fail, we must look to the general causes, especially bearing in mind the possibility of hereditary syphilis, of malarial, paludal, saturnine, or rheumatic toxæmia. The possibility of poisoning from patent medicines, etc., should not be overlooked. The hygiene of the house should be examined into, not inquired into, as well as the diet. Should there still be no tangible cause for the seizures, we would put the child upon a diet of peptonized milk exclusively, and give $\frac{1}{50}$ grain of corrosive sublimate, four times daily, keeping the child in bed for three weeks; applying a thin strip of fly blister to the lumbar spine once every five days. W. F. W.]

Society Notes.

AT the American Climatological Association meeting at Boston, Drs. C. W. Townshend and A. Coolidge, Jr., Boston, presented a paper on

THE MORTALITY OF ACUTE LOBAR PNEUMONIA;

a study of all the cases treated at the Massachusetts General Hospital from the first case in 1822 to the present time.

SUMMARY.

1. In the one thousand cases of acute lobar-pneumonia treated at the Massachusetts General Hospital from 1822 to 1889 there was a mortality of 25 per cent.

2. The mortality has gradually increased from 10 per cent. in the first decade to 28 per cent. in the present.

3. This increase is deceptive from the following reasons, all of which were shown to be causes of a large mortality:

(*a*) The average age of the patients has been increasing from the first to the last decade.

(*b*) The relative number of complicated and delicate cases has increased.

(*c*) The relative number of intemperate cases has increased.

(*d*) The relative number of foreigners has increased.

4. These causes are sufficient to explain the entire rise in the mortality.

5. Treatment, which was heroic before 1850, transitional between 1850 and 1860, and expectant and sustaining since 1860, has not, therefore, influenced the mortality rate.

6. Treatment has not influenced the duration of the disease or of its convalescence.

CONCUSSION OF THE SPINE.

In his paper read at the American Medical Association the following conclusions were announced by Dr. H. H. Smith:

1. Concussion of the spine is no longer a matter of doubt, but may sometimes occur as the result of various forms of violence, there being nothing peculiar in the application of the force to the body, as the result of derailment or collision of railroad trains.

2. The pathological changes noted in the molecular structure of the cord as the result of shaking, jaring, or so-called concussion of the cord, when attended by paralytic symptoms, may be due to hemorrhagic effusion, or be shown post-mortem in softening or localized or limited atrophy. In cases due to hemorrhage the symptoms may be improved by judicious treatment, and permanent disability prevented.

3. The possibility of preëxisting neurasthenia, or hysteria, or fraud on the part of a claimant, should be carefully noted in forming a diagnosis in these cases.

4. As the question of permanent disability, justifying exemplary damages, is frequently raised in claims of the kind alluded to, it should be recollected in forming a prognosis that numerous cases are reported of recovery or marked improvement in a few weeks, and one in three years, even after the occurrence of paralysis.

5. No physician should go into court and swear that a plaintiff has had a concussion of the spinal cord or of its nerves, unless he has proved the disturbance of the normal function of the cord, as shown in sensation or motion, or both, and that the symptoms appeared *soon* after the injury.

FRACTURES OF THE SPINE.

Dandridge, in an able paper read before the surgical section of the American Medical Association, reached the following conclusions as to the treatment of these fractures:

1. In fractures of the cervical vertebræ, there is indicated immediate reduction of any displacement by extension and manipulation under an anæsthetic, followed by continuous extension and immobilization.

2. In all fractures of the lumbar or dorsal spine, involving the bodies or the arches, reduction is effected, with or without the plaster-jacket by the hammock suspension preceded, if there is evident displacement, by extension under an anæsthetic.

3. When symptoms indicating injury of the cord persist without improvement, resection is indicated.

4. Immediate operation would be indicated when there is marked depression of the arches with symptoms of paralysis.

5. Long continuance of the symptoms is not in itself a contra-indication to operation.

6. We have, in suspension, the means of alleviating some of the sequelæ of fracture of the spine.

EXTROVERSION OF THE BLADDER.

Porter gives the following rules, in operations for the relief of this condition:

1. All the general rules of plastic surgery hold in these operations. The flaps must be about one-third larger than the gap to be filled.

2. They must be arranged in such a manner as to furnish to the pedicles an abundant supply of blood.

3. During delays in the operation they should be covered with hot towels wet in an antiseptic solution.

4. They must be handled as little as possible, and rarely with forceps.

5. Any dragging on the pedicle endangers the vitality of the flap.

6. All bleeding must be arrested before the flaps are adjusted in position.

7. Light and gentle compression prevents any oozing between them.

8. The operation completed, they should be kept for many hours under moist, hot, antiseptic dressings.

9. Perfect antisepsis should be maintained throughout.

Dr. Robert T. Morris, of New York, read a paper entitled

WHAT DRESSING SHALL LIE NEXT THE WOUND?

Vaseline or oil spread upon any textile fabric represents the worst type of dressing, because the unguent mingles with the discharges and retards organization; because the textile fabric entangles new epithelium cells and connective-tissue cells, and because there is nothing in the dressing to prevent fermentation and wound infection. Lint and cotton are even worse than textile fabrics.

The cerates spread upon textile fabrics are one point better, in that new epithelium and connective-tissue cells are not entangled in the mesh.

Balsams spread upon textile fabrics, or upon lint or cotton, are better than vaseline or cerate, because they may limit fermentation.

There are only two perfect types of dressing. The iodoform covering for small wounds represents one of these. Iodoform forms a thin, firm coagulum with lymph, and this is not easily attacked by microörganisms. Beneath this coagulum the processes of repair go on smoothly in small wounds, even when a certain number of microbes are at work, because the iodoform neutralizes the ptomaines.

The other perfect dressing is the one suitable for larger wounds, and it possesses the following properties: First, smoothness, and impenetrability to new epithelium and connective-tissue cells (Lister's protective oiled silk). Second, a bulky mass which is highly absorptive, to draw serum away from the wound, and to make it too dry for microbe food; and this dressing is charged with antiseptics to destroy microörganisms (bichloride cotton or gauze).

We regret to announce that Dr. George M. Gould will be prevented by the pressure of private business from continuing his contributions.

Book Reviews.

DIPHTHERIA: its Nature and Treatment. By C. C. BILLINGTON, M.D., and INTUBATION IN CROUP, and other Acute and Chronic Forms of Stenosis of the Larynx. By JOSEPH O'DWYER, M.D. Octavo, 326 pages. Price, muslin, $2.20. New York: William Wood & Co.

The author does not claim to have written an exhaustive treatise on the subject he has chosen, yet he has added a valuable contribution to the bibliography of this grave disease. The etiology of diphtheria, in spite of the attention given, is still in doubt. In fact there seems to be but little certainly known of the disease. Some consider it first to be purely local, and afterwards, through absorption of the septic products, to become constitutional; others, again, consider diphtheria to be constitutional from the first, and to make the pharynx its "site of election."

All so-called membranous croup is held by some to be simply diphtheria of the larynx; whilst others scout such an idea as nonsense.

There are others, again, conservatives, who believe that there is such a disease as membranous croup, but that it is very rare, and that many cases so described are in reality diphtheria. To this latter class belongs our author. He says: "Simple membranous croup is a comparatively rare form of disease. In regions in which diphtheria is endemic or epidemic, the two affections are so likely to be inter-complicated or confounded that the distinction is practically worthless." Dr. Billington ranks himself also among those who believe that diphtheria is primarily a local affection, and cites a number of clinical facts to prove his point.

The article contributed by Dr. O'Dwyer on Intubation in Croup adds much to the interest and value of the book.

The technique of the operation and all the indications for and against it, are fully and plainly set forth.

KIRKE'S HANDBOOK OF PHYSIOLOGY. By W. MORRANT BAKER, F.R.C.S., ETC., ETC., and VINCENT DORMER HARRIS, M.D., ETC. New York: William Wood & Co. Twelfth edition. Revised and rewritten, making a presentable volume of about 750 pages, and with 500 illustrations.

This old friend comes to us with much of the freshness of a new book, having been largely rewritten. The object of the publishers seems to be to make, for a moderate price, a good and reliable assistant for the student during his college days, when time is precious and something is demanded to supplement the regular lectures. The book is of moderate size, and so arranged that the elementary portion is printed from larger type, thus facilitating the making of an expeditious review. It, in fact, has the advantages of a compendium without many of the objectionable features; it encourages and invites the student to drink deeper, and, at all times, tempts him by the proximity and piquancy of the draught.

The wood-cuts, with which the book is supplied liberally, are distinct and well chosen to illustrate the subjects; if not quite as fine as works of art might be, they answer the essential requirement of illustrating the text. The type and paper are fair.

The book in its opening chapter treats, by successive steps, of the general phenomena of life, beginning with those of protoplasm. Differentiation between plants and animals, always a stumbling block for the beginner, follows. The morphological development and the division of functions are treated of, commencing with the blastoderm and regularly passing to the elementary structures and the various forms of cells composing them, which are described and well illustrated, frequently by means of cuts from standard histologists.

The next portion is devoted to a description of the blood, its corpuscles, its physical and chemical characters, its development and uses. This is succeeded by the consideration of the circulation, and includes the study of the heart, arteries, veins, and capillaries, their distribution and functions. Respiration is very satisfactorily treated, its importance being acknowledged, but food and diet, which might be dwelt upon with great profit, have been allotted only a short and seemingly too brief space, although the matter is well chosen. Digestion, absorption, and secretion occupy about one hundred and twenty pages; in this the teeth, salivary glands, stomach, liver, pancreas, the intestines and their various glands, are described; the physiological functions and the relations of them and the organs to each other are completely and very tersely given. The skin, kidneys, vascular glands, and muscular system are then described in an able epitome.

The nervous system receives the principal attention, as its importance and the recent discoveries warrant, comprising nearly one-third of the book. The different motor centers of the cortex of the brain are described and illustrated with a view to facilitate the diagnosis of brain lesions and to guide in the surgical efforts for their cure, which are bidding for an exalted position in the treatment of many affections heretofore incurable and often frightfully painful. Indeed, the appalling sufferings, so long the reproach of the healing art, at one time embraced under the obscure general title of neuralgia, of late frequently are completely cured as a result of the skilful and thoroughly educated surgeons' abilities to discover the location of abnormal growths or deposits, which was only possible when guided, as they have been, by the science of physiology.

The generative organs are minutely studied, and many of the features of development are explained to the reader in a masterly manner.

A chapter "on the relation of life to other forces" is both interesting and instructive, in that it deals with some similarities of correlation of force or energy in machines and organized bodies. In this the task of persevering in the unfolding of the enigmas of life or vital action is bravely attempted, and although it seems to be acknowledged by the author as elusive, yet he holds to the conclusion that it is a duty to push onward without discouragement, evidently impressed with a belief that some day the problem will be solved.

Finally, an appendix furnishes much of the organic

chemistry that many writers weaken their works by attempting to introduce in the bodies of them, where it seems more likely to discourage the young student than to interest him.

In the method of arrangement of this book appears to lie one of the strongest recommendations for its publication. Indeed, the work may be most justly commended, and college students or busy practitioners will find in it *multum in parvo*. We doubt not that the book will find a ready sale, from the fact that its simplicity will make it popular; being comparatively free from the much involved, prolix and over-conscientious effort to explain physiological phenomena, which embarrass the general student.

T. C. S.

CYCLOPÆDIA OF THE DISEASES OF CHILDREN, MEDICAL AND SURGICAL. Edited by JOHN M. KEATING, M.D. Vol. I. J. B. Lippincott & Company.

The diseases of children are perhaps the most difficult of all human ills to rightly understand and properly characterize. Every new book which really sheds fresh light upon this now special department of medical science is to be encouraged and welcomed. The present work will be issued serially in four large volumes, the first of which has recently appeared. In its scope it is truly cyclopædic, a fact which will tend to diminish its usefulness so far as relates to the needs of the general practitioner, to whom a more concise statement of well-established facts would, for obvious reasons, be preferable. By the so-called specialist in children's diseases, however, the appearance of this work will be hailed with peculiar delight; for the latter, unlike the busy family doctor, seeks to regale himself with the foremost speculations of cotemporary medical literature bearing upon his favorite line of study, and to this end this book promises to provide for him abundantly. And from the hands of the student of pædiatrics this work will doubtless receive unlimited praise. The general practitioner, however, will frequently have occasion to employ this colossal work, referentially. It should not fail, therefore, to find a place in all of our leading American medical libraries.

The method pursued by the editor in selecting authors, many of whom are widely-known specialists, with sole regard to their peculiar fitness to discuss the subjects assigned to them, has its obvious advantages, and this is a pretty good guarantee that the book throughout will contain sound instruction. It is given to but very few, if any, writers, even though they be rarely gifted specialists in this broad domain, to become the satisfactory exponent of a product so comprehensive in all its elements as the book under discussion.

The present volume contains 990 pages. The introductory chapter is contributed by Prof. A. Jacobi, who points out clearly, in a general way, the differences in the behavior of the various organs of the body while the child is passing through the different stages of its development, and that these anatomical and physiological differences greatly affect the course and symptomatology of children's diseases as well as the frequency of their occurrence. He also calls attention to the important practical fact that certain malformations and maladies occur only in early childhood. But most of the points brought forward in the introductory are more fully presented in the first two articles under Part I, namely, "On the Anatomy of Children," by George McClellan, M.D., and "The Physiology of Infancy," by Angel Money, M.D. In discussing the anatomy of the abdomen, McClellan very properly describes fully the nerve supply, since the symptoms relating to the diseases of childhood can in numerous instances be interpreted only through a knowledge of the position of the nerves. In a work of this sort to devote a special chapter to diagnosis might be considered not entirely relevant, but the advice given on this head is for the most part excellent, particularly on the method of examining sick children. And Dr. Finlayson has also given prominence to a fact of prime importance, namely, that special tendencies to acute diseases are inherited just as certainly as that chronic disorders are transmitted from generation to generation.

Since the subject of the relation of bacteria to disease has come to occupy a foremost position, its presentation in a particular manner by Dr. Shakespeare, a zealous worker in this field of investigation, will be heartily received by the profession.

The popular belief in maternal impressions is fully supported by Dr. Wm. C. Dabney, who gives us some important conclusions, drawn from actual facts, which he subjoins in a large general table. Dr. Barton Cooke Hirst handles "Diseases of the Fœtus" with a masterly hand. There is much practical information contained in the chapter which treats of "The Child at Birth and Immediately Thereafter," contributed by Prof. R. A. F. Penrose.

Prof. Parvin furnishes a lucid statement of the "Injuries of the Newborn," in which he points out the too little known fact that in instrumental deliveries injuries are not only at times inflicted upon the head externally, but also upon the meningeal vessels, causing hemorrhage and death.

A large share of attention is quite befittingly devoted to infant feeding. Space would fail us were we to attempt to examine in detail Dr. Rotch's able exposition of this important theme. We feel constrained, however, to add that the reader will find in the author's division of artificial foods, and his discussion thereon, all that is needful to serve as a reliable guide in the employment of an indispensable class of preparations.

The following subjects, Wet-nurses, Diet after Weaning, Nursing of Sick Children, Nursery Hygiene, Dentition, and Puberty; its Pathology and Hygiene, are all cleverly, though briefly, examined by as many different writers.

Part II is dedicated chiefly to the consideration of fevers and miasmatic diseases, and among the many individual affections treated, and their well-known authors, respectively, are, Enteric Fever, by J. C. Wilson, M.D.; Typhus Fever, by Alexander Collie, M.D.; Relapsing Fever, by R. G. Curtin, M.D.; Cerebro-spinal Fever and Diphtheria, by J. Lewis

Smith, M.D.; Scarlet Fever, by S. Busey, M.D.; Measles, by Dr. Waxham; Rheumatism, by W. B. Cheadle, M.D., F.R.C.P.; Malaria, by T. Forchheimer, M.D.; and Yellow Fever, by John Guiteras, M.D. The majority of the special diseases are treated with a degree of fulness commensurate with their leading practical importance; a few, however, are not, notably, scarlet fever.

It is gratifying to see it recommended in doubtful cases of malaria to examine the blood for plasmodium. In describing the treatment of pertussis, Dr. Dolan does not mention the use of antifebrin, which has a peculiarly favorable influence upon the severity and the frequency of the paroxysms, in careful hands. In his chapter on Vaccination, Dr. W. T. Plant does not advise against the use of humanized virus, but tells us how, in his opinion, the danger from the transmission of disease can be avoided. In short, the truth is, however, that no precautionary measure can insure immunity in every instance, and the only adequate safeguard to society lies in the use of bovine virus. Dr. Wm. Wright Jaggard adds an article of great scientific interest on Joined Twins, and Dr. H. Y. Jayne one of equal merit, on Embryology. Prof. Roberts Bartholow concludes the present volume by a charming discourse upon the General Therapeutics of Children's Diseases, in which he, at the outset, takes occasion to direct attention to the fact that, "Whatever hold homœopathy has acquired, is due, for the most part, to the sugar pellets, tasteless solutions, and other contrivances for rendering the administration of medicines a pleasure rather than a pain." He continues: "Our efforts should be directed to the preparation of efficient remedies that shall be also without disagreeable qualities."

Many of the subjects treated in this volume are further elucidated by means of numerous good illustrations. The publishers, in issuing this work, have given us a creditable example of American book-making.

J. M. A.

Gleanings.

THE PREVENTION OF MIGRAINE.—Dr. Hammerschlag has never been disappointed in the use of the following combination for preventing sick headache:

℞.—Caffein citrat.	1.00 = gr. xv.
Phenacetin	2.00 = ʒss.
Sacchar. alb.	1.00 = gr. xv.

M.—Ft. pulv. div. in dos. æqual. No. X. Divid. in capsul. amylac.

Sig.—One capsule every two to three hours during the interval between the attacks.—*Allg. Med. Centrl. Ztg.*, No. 39.

FROMENTINE.—A French chemist named Beaumetz exhibited at a recent meeting of the Paris Academy of Medicine a new alimentary substance, which he names fromentine. It is obtained from wheat by the aid of special millstones, and is really the embryo of the wheat reduced to flour. It contains three times more nitrogenous substance than meat, and a large proportion of sugar. It is thought that it may advantageously replace powdered meat as a concentrated food. It may be employed for making soups, and even for making biscuits.—*Am. Anal.*

ENURESIS AS A HABIT.—When such is the case successes have been reported by closing the meatus urinarius with collodion at night.

WATER IN THE LUNGS.—Bowles (London *Lancet*) says that contrary to the general belief that water does not enter the lungs of those drowned, on account of closure of the epiglottis, he has found water a number of times in the lungs of both animals and human beings who died by drowning; and therefore holds that the Sylvester method of resuscitation is not to be relied on.

ALCOHOLIC PARALYSIS.—Ross (London *Lancet*), thinks that these three symptoms are generally to be found in a coming case of alcoholic paralysis, often long before any of the graver manifestations, and may thus be of much aid, especially in cases where no history of alcohol drinking is known. The first is numbness of the fingers and toes; second, vasomotor spasm of the extremities, Reynand's local asphyxia, giving rise to deadness and coldness of the fingers and toes; third, severe cramps, most frequent and severe in the muscles of the calf.

DANGER OF GIVING CHLOROFORM BY GAS-LIGHT.—Ball (*The Practitioner*), adds to the cases already reported a number of others showing the disagreeable and even dangerous symptoms that may arise, both to the patient and the bystanders, in using chloroform by gas-light. A strong irritant is produced under such circumstances, which has been found to be carbon oxychloride, or phosgene gas. The symptoms are paroxysms of coughing, a sense of choking and irritation in the throat, giddy feeling, and, after a time, a strangling and burning sensation over the larynx.

PREVENTIVE INOCULATION.—M. Roux, on behalf of M. Pasteur, gave the Croonian lecture on this subject. The lecture is an able *résumé* of Pasteur's work in this particular direction. With regard to inoculating for hydrophobia, M. Roux says that 6870 persons have undergone the treatment at the Paris Institute since July, 1885, and that of this number the mortality has been only 1 per cent., against that of 15 per cent. which usually follows the bites of rabid animals. He considers that the violent attacks which have been made against the practice are without any just foundation.

THE family of Dr. Chas. T. E. Ritter, of No. 188 Mercale Street, New York City, who was found dead in bed, 8 o'clock June 20, discredit the rumor that he committed suicide. The Doctor had suffered heart disease for some time. He attended the dinner at the opening of the Brooklyn Throat Hospital, Wednesday night and it is thought that the unusual excitement brought on an attack of his ailment. Coroner Lindsay thinks that death was due to natural causes.

AN EXTRAORDINARY EXPERIMENT AND ITS RESULTS.—At the Société de Biologie, M. Brown-Séquard made a very curious communication which will admit of very different interpretations. He said that he had been lately making experiments of a very interesting nature. Guided by certain theoretical ideas, he extracted the liquid from the testicles of animals and injected it into other animals, and finally *into himself*. The effect on the animals he was not able to fully understand, but he could give an account of what he himself experienced. As to the immediate effect of the injection he would not say more than that a certain amount of inflammation followed, which, however, never went on to suppuration. After some time he felt himself becoming a new man, constipation from which he suffered for several years disappeared as if by enchantment, urinary troubles which gave him for some time much uneasiness ceased almost immediately, and not only that, but strength returned to his legs, so that he can remain standing for hours together without fatigue. His intellectual powers were also greatly stimulated, and, in fact, he declared that he felt himself at least *thirty years younger*. He discreetly threw out a hint as to the other functions which were revived by these experiments! M. Brown-Sèquard concluded by saying, that it might be thought he was dreaming, or suffering under a delusion, but he assured them he was not, and he maintained exactly what he reported. A member mildly suggested that the fever produced by the irritating liquid injected may have produced in a certain sense the phenomena, but he was immediately sat on by the eminent physiologist. Perhaps, with all respect, the well-known words of Governor Felix to St. Paul might be used with more truth towards our learned friend.—*Med. Press.*

DR. L. B. BAKER, a prominent physician of Beebe, Arkansas, was recently married to Miss Mollie Hines, of Newport, Arkansas.

DR. LOUIS FRANK, resident graduate of the Louisville City Hospital has resigned that position and has been succeeded by Dr. Chas. B. Smith, of Millersberg. Dr. Frank and wife start at once for Strasburg, Germany, where the doctor will take a two years' course in medicine.

A meeting of Wyoming county physicians was held in Warsaw, Tuesday afternoon last week. A committee consisting of Drs. Palmer, of Pike, Rae of Portageville, and Lush of Warsaw, were appointed to make arrangements for the meeting to be held at the Cascade House, Portage, in September.

THE members of the Rochester Pathological Society held their annual election of officers at the Genessee Valley Club House, Rochester, New York, Thursday Evening last. Dr. Benjamin Wilson was elected President; Dr. E. T. Dow, Vice-President; Dr. Ogden Bachus, Secretary. Dr. E. W. Mullegan, the retiring president read a paper on Microscopy in Medicine.

THE *Maritime Medical News* gives an interesting chart, covering four generations of a family's history, and beautifully illustrating the heredity of a neurotic taint, and the interchangeability of neuroses.

Descendants of Amos M. No inf. rmation about parents.

A. M., one of six children, of whom two, A. M. and D. M., had progressive muscular atrophy.

A. M. had eleven children, of whom five had progressive muscular atrophy, and seven either had it or transmitted the disease. These considered *seriatim:*

H. M. had two children; M. E., progressive muscular atrophy, and she had one daughter (fourth generation) blind; and A. M., who died of epilepsy.

A. M., 2, had progressive muscular atrophy, but his family was exempted.

J. M. had a large family, but no information was obtained.

N. T., progressive muscular atrophy, and of her children, two had same disease, one died of epilepsy, one insane, two died suddenly, others healthy.

E. M., family exempted.

S. W., progressive muscular atrophy, had three children, of whom two had same disease, and the third insane. W. W.'s children, numbering four (fourth generation) all suffer from nervous troubles.

E. B., progressive muscular atrophy, but family exempt.

H. T., two children, both with progressive muscular atrophy. Mrs. H. has eight of a family (fourth generation), of whom two are idiotic.

C. H., family exempt.

I. H., family exempt.

D. B., progressive muscular atrophy, had one child with same disease, and she had a child (fourth generation) with it. Of other members: one died young, one of diabetes, seven of phthisis; three are in good health.

Descendants of David M.

D. M., progressive muscular atrophy, had eleven children, of whom three had same disease. Family considered *seriatim:*

R. M., family exempt.

R. C. died of tumor of stomach; family exempt.

R. M. died of dropsy.

J. M. died of liver disease. Nothing known of family.

T. M. died of old age. Nothing known of family.

S. H., progressive muscular atrophy, had seven children, of whom four had same disease.

N. H. has large family, one epileptic.

D. H., progressive muscular atrophy.

H. H., no family.

M. C., progressive muscular atrophy, had three children (fourth generation), of whom two had same disease.

R. S. had one idiotic; rest of family exempt.

J. H., progressive muscular atrophy, had one son with same disease.

W. H., progressive muscular atrophy.

D. M. died of old age. Nothing known of family.

A. M., living. Nothing known of family.

R. M., nothing known of family.

A. S., progressive muscular atrophy, family exempt.

M. W., progressive muscular atrophy; one son with same disease.

Medical News and Miscellany.

Dr. Mecklenburg Polk has a farm on Long Island.

The sanitary condition of Atlantic City is said to be good.

Dr. Joseph W. Howe, of New York, expects to sail for Europe in August.

Dr. A. R. Blair, one of York's oldest and most respected citizens, is seriously ill.

Dr. Hermann M. Biggs, of New York, who is in Europe, is expected back in August.

Dr. William H. Thompson, of New York, becomes a Connecticut farmer during the heated term.

Three men on the bark "Samar," from Tamatave, are reported to have died on the voyage, from beriberi.

The American Pharmaceutical Association lately met in San Francisco, with an attendance of 375 delegates.

Dr. Lewis A. Sayre is still at the Hot Springs, Virginia, where he has been recuperating for several months.

Dr. Ernest B. Sangree was lately appointed vaccine physician in the third district, *vice* Dr. Williams, deceased.

The Presbyterian Hospital is in luck; it has lately had $150,000 given it for the purpose of making certain additions.

Dr. Francis M. Perkins married Miss Franc Arnold Walker, June 19, 1889, in Plymouth Church, Brooklyn, N. Y.

There were 400 deaths in Philadelphia for the week ending June 24, against 389 for the corresponding week of last year.

Dr. Frederic S. Dennis, of New York, has a cottage at Elberon, Long Branch, where he usually spends his summers.

If our city street contractors were made to live on some of the little back streets, these by ways would be less odorous than at present.

The number of inmates in the Philadelphia Almshouse is 2814; in the Philadelphia Hospital, 971, and in the Insane Department, 807.

Dr. Charles A. Doremus has a cottage at Pelham, a fashionable settlement on the north shore of Long Island Sound, near New Rochelle.

Dr. Austin Flint will not take any long vacation away from New York, as he is on duty at Bellevue Hospital during July and August.

The preliminary Announcement is out of the American Public Health Association, which holds its seventeenth annual meeting at Brooklyn, N. Y., October 22, 23, 24, 25, 1889. Among the desiderata we notice that "all papers must be either printed, type written, or in plain handwriting."

An epidemic of malignant diphtheria has broken out in Carbondale. In one family four children are lying at death's door, and in another three.

The $25,000 that the Legislature did not give for the new hospital, the Hahnemannians intend to try to raise next fall by means of some entertainment.

A London health inspector reported that a number of cases of diphtheria had been caused by cats going from house to house, and thus carrying the virus.

Drs. George Woolsey and C. G. Coakley are lecturers on Anatomy at the University Medical College, New York, but the Chair of Anatomy is not yet filled.

Peter D. Keyser, A.M., M.D., Professor of Ophthalmology in the Medico-Chirurgical College, has lately been appointed a member of the City Board of Health.

The Johnstown physicians proper are beginning to object to the various society physicians stationed there, as they say that the latter are treating every one regardless of ability to pay.

Dr. A. E. MacDonald, General Superintendent of the New York City Asylums for the Insane, will give the greater part of his time this summer to the farm for the insane at Islip, L. I.

A Western paper, speaking of a man who carries a bullet in one side of his head to the great detriment of his memory, says that he frequently harnesses one side of a horse and forgets the other.

They are now making examinations in England and Germany of the various floor deafeners, with the result of finding that they are perfect mines of bacteria, and manufactories of bad smells.

The entire extent of Long Island is a favorite resort for New York physicians in summer, and Bay Shore, on the Great South Bay, just inside of Fire Island light, is especially popular with them.

John V. Shoemaker, A.M., M.D., and John Aulde, M.D., are engaged on a "Treatise on Materia Medica, Pharmacology, and Therapeutics," which they expect to have out in the early autumn.

Surgeon Parry, of the East Indian Medical Department, says that he saw the jet-black hair of a rebel Sepoy turn gray in an hour while he was under examination and half mad with fear.—*Times.*

Dr. John W. De Witt, of St. George's and Drs. Howard Ogle and Peter Cooper, of Wilmington, Del., have been appointed a Board of Examining Surgeons for pension applicants of the Wilmington district.

A dispatch from Ottawa, Ont., says that at Cape Breton, last week, Dr. Smith discovered four cases of leprosy. A case was reported to him in 1885, and he is severely censured by the authorities for having allowed the disease to go on without investigation until within a few days. The four victims have been removed to Tracadie Lazaretto, where there are already nineteen patients.—*Ledger.*

THE water-shed from which New York's Croton water is collected covers 361 square miles; and it is computed that 18,500 cows, pigs, horses, and sheep live on that shed. The relation between these two facts is obvious.

ACCORDING to the figures, proportionately less die in New York tenement houses than in the more desirable localities; but in this case we think the figures have gone back on the well-worn adage with respect to their truthfulness.

THE Philadelphia Board of Health has received a complaint of the sanitary condition of the public school building at Third and Lombard Streets. It is said that three of the teachers and a number of pupils are now ill.

DR. RUDOLPH A. WITTHAUS, Professor of Chemistry and Physics at the University Medical College, is now lecturing in the Medical Department of the University of Vermont at Burlington. He returns to New York on July 20.

THE Pennsylvania Railroad has just issued stringent rules with regard to the sanitary condition of all their property, rolling stock, and the like. Everything must be kept scrupulously clean, and disinfected when necessary.

THE entire family of Thomas Dunn, of Smith Street, Belleville, N. J., has died within ten days. On Friday, the 14th ult., one of his four children died of diphtheria, another died the following day, another last Friday, and the fourth yesterday.

ACCORDING to a daily paper, Judge Pratt, of Brooklyn, awarded $12,000 damages to a woman as a salve for her wounded feelings (it says health, but that couldn't be), hurt by taking five grains of calomel from a steamship's surgeon instead of quinine.

THE graduates from the University Medical College, who go to Bellevue Hospital this year, are H. L. Constable, of Ohio, W. E. Chau, of New Jersey, M. M. Rodriguez, of Central America, G. C. Pope, of New York, and C. H. Towlerton, of New York.

DR. CHARLES INSLEE PARDEE, Dean of the University Medical College, New York, splices his tarry toplights with great facility, now that he has developed into a yachtsman. Dr. Pardee is a hard worker and seldom leaves his desk at the college for more than a day or two at a time in summer.

IT looks as though the Pneumatic Cabinet, after a brief but troubled struggle with a cold world, had lain down for a prolonged rest.

"Whines of Coca!" That is what the besieged doctor calls them, as he listens to the plaintive appeals of rival manufacturers for his favorable consideration.

ANOTHER instance is reported of a child who found its mother's pill-box, loaded with one hundred pellets of quinine and strychnine, and straightway ate thirty or forty of them under a false impression. The Coroner held the usual inquest.

We wonder when mothers will take at least as much care to keep poison out of their childrens' way as they do with candy.

DR. GEORGE PATTEN BIGGS and Dr. Louis Raush, both of New York, who graduated at Bellevue this spring, were among the successful candidates for appointment in Bellevue Hospital and enter its service next October. The other successful candidates were Dr. Austin Flint, Jr., and Dr. George David Stewart, who began work at the hospital in April.

THE newly constituted Board of Health of Lancaster, Pa., consisting of William A. Morton, Dr. R. M. Bolenius, Dr. D. R. McCormick, M. F. Steigerwalt, and S. H. Zahm, organized by electing William A. Morton President, Jacob Halbach, Secretary, and Dr. Walter Boardman, Health Commissioner.

—*Daily Paper.*

DR. THOMAS M. MARKOE, who has been chosen Vice-President of the College of Physicians and Surgeons, has been a medical professor in New York for nearly half a century, and is now seventy years of age. As a lecturer he has always been regarded with the highest favor by the students of this college, which is now the best equipped institution of its kind in the United States.—*Times.*

FOUR sons of members of the Faculty of the Bellevue Hospital Medical College are assistants to chairs in that institution; viz., Dr. Charles A. Doremus, Professor Adjunct to the Chair of Chemistry and Toxicology; Dr. Reginald H. Sayre, Assistant to the Chair of Surgery; Dr. Lewis Hall Sayre, Assistant to the Orthopædic Surgean, and Dr. Austin Flint, Jr., Assistant to the Chair of Physiology.

THE New York Post-Graduate School has acquired title to the property which it occupies, valued at $90,000. Dr. Lindsay, of the Post-Graduate, has made a photograph of the professors of this institution, having first taken separate pictures and then photographed the heads together upon a simple plate. The pictures are better likenesses, and are sharper in their outlines than are generally seen in such a group.

DR. A. W. WILKINSON will be well and kindly remembered as the assistant of Dr. Doremus for a long time at Bellevue Hospital Medical College, and the College of the City of New York. Dr. Wilkinson gave up this position about twelve years ago and became the chemist of the Mutual Gas Company. When that Company, with the others in New York, formed the "Consolidated," Dr. Wilkinson's services were retained, and I understand that he was paid $250,000 for a single invention which he sold that able business organization.

THERE is an opinion that those in control of the Training School for Female Nurses on East Twenty-sixth Street, New York, nearly opposite the entrance to Bellevue Hospital, are looking with longing eyes at the new building of the Mills Training School for Male Nurses. The male nurses are getting their training from the female nurses, and it is said that the hospital doctors do not bestow as much friendly attention upon the members of the Training School for Men as they do upon the young women from over the way.

The Pharmacy Section, American Medical Association.

In the exhibit room, back of the Ocean House, were to be found specimens of the skill of nearly all our leading manufacturers. There was evidently an overstock of samples, owing to the small attendance of physicians. Among the preparations which were offered to the visitors were the following:

Maltine Manufacturing Co., 54 Warren Street, New York.
Maltine, plain and variously medicated.

J. P. Bush & Co., 2 Barclay Street, New York.
Bovinine.

Thomas Leeming & Sons, 18 College Place, New York.
Nestle's milk food and condensed milk.

Provident Chemical Co., St. Louis, Mo.
Crystalline phosphate.

Reed & Carnrick, 447 Greenwich Street, New York.
Beef peptonoids, powdered and liquid.
Soluble foods.
Lacto-preparata.
Pancro-bilin, pills and liquid.
Bromo-pyrine.

Lambert Pharmacal Co., St. Louis, Mo.
Lithiated Hydrangea.
Listerine.

W. H. Schieffelin & Co., 178 William Street, New York.
Pills of salol.
" phenacetine.

New York and Chicago Chemical Co., 98 Maiden Lane, New York.
Golden scale pepsin.
Ford's pepsin.
London essence of beef.

Carl L. Jensen Co., 100 Maiden Lane, N. Y.
Jensen's crystal pepsin.

H. Bernd & Co., 2631 Chestnut Street, St. Louis, Mo.
Sample leaves of physicians' registers.

Tarrant & Co., 280 Greenwich Street, New York.
Genuine imported Hoff's malt extract.
Seltzer aperient.

Henry B. Platt, 36 Platt Street, New York.
Platt's Chlorides.

Malted Milk Co., Racine, Wis.
Malted milk.

Doliber-Goodale Co.
Mellin's food, etc.

New York Pharmaceutical Co., New Bedford, Mass.
Hayden's viburnum comp.

John Wyeth & Bro., Philadelphia.
Troches of comp. licorice powder.
" Jamaica ginger.
" Jackson's pectoral.
Hypodermic tablets of morphine.
Soda-mint.
Compressed pills, antibilious.
" " quinine.
" " laxative.
" " morphine and atropine.
" " calomel.
Peptonic pills.
Extract of malt.
Fluid extract buchu.
" " valerian.
" " digitalis.
" " alterative.

C. S. Baker & Co., Chicago, Ill.
Rose's peptonized beef.
" " " and cod-liver oil.
Nitrogenized iron, alone and compounded variously.

Chesebrough Manufacturing Co., New York.
Vaseline in all forms, pomade, cold cream, etc.

The Upjohn Co., Kalamazoo, Mich.
Pills of creasote.
" quinine.
" for migraine.

Beeman Chemical Co., Cleveland, Ohio.
Pure pepsin.

Caswell, Massey & Co., New York.
Quinine chocolates.

Hazard, Hazard & Co., New York.
Elixirs.
Hypodermic tablets.

Rigaud & Chapoteaut, Paris, France.
Peptone wine.
" powder.
Capsules of dialysed pepsin.
" morrhuol.
" santal-midy.
" creasote.
" valerianic ether.

Keasbey & Mattison.
Bromo-caffeine.

Johnson & Johnson,
Plasters, lint, cotton, gauze, ligatures, and surgeons' supplies, too numerous to mention.

The Rudisch Co., Greenwich Street, New York.
Rudisch's sarco-peptones.

Armour & Co., Chicago, Ill.
Extract of beef, liquid and solid.

Liebig Co.
Extract of beef.

Wm. R. Warner & Co.
Miscellaneous preparations.

Hance Bros. & White.
Miscellaneous preparations.

Seabury & Johnson.
Surgeons' appliances.

Chidsey & Partridge, Boston.
Surgeons' appliances.

Dr. Daggett, Buffalo, N. Y.
New and improved gynæcological table.

Waite & Bartlett, New York.
Batteries.

Galvano-faradic Co., New York.
Batteries.

Morris Earle & Co.
Microscopes.

Murdock Co.
Liquid food and suppositories.

Eisner & Mendelsohn.
Hoff's malt extract.
Carlsbad water and salt.

D. Appleton & Co., New York.
Books, journals, etc.

Lea Bros., Philadelphia.
Books, journals, etc.
F. A. Davis & Co., Philadelphia.
Books, journals, etc.
Mrs. E. D. Staples, West New Brighton, Staten Island, N. Y.
Invalid cot.
C. H. Phillips Co., New York.
Cocoa and elegant pharmaceuticals.
McKerson & Robbins, New York.
Pills and preparations.

And last, but by no means least, THE TIMES AND REGISTER, the only medical journal which had the enterprise to go into the exhibit, and pay for space and have an agent to attend to its interests. Out of 2000 copies sent to the meeting only about 200 were brought back, so that each member present must have carried away at least two copies. The other journals present appeared in their legitimate place, as side issues to the publishing houses. The New York *Medical Record* excited considerable amusement, because a card in the hotel office stated that *a copy* of the *Record* could be found in the reading room, which was to be returned after it was perused. This was taken to be Wood's contribution to the meeting, but, in fact, the card had occupied its place for several years, similar ones being posted in all the summer hotels.

While the display made by the manufacturers was not so extensive as usual, it was unusually attractive, nearly all the largest firms being represented.

The exhibit of the Maltine Company, occupying, as it did, one of the prominent locations in the building, attracted universal attention. The exhibit was constantly surrounded by inquiring physicians, and, judging from the number of samples presented, maltine was well advertised in this *legitimate* way.

In direct contrast to the vari-colored displays of bunting and banners appeared the exhibit of the Swiss house of Henri Nestlé, represented by Thomas Leeming & Co. Situated near the door on the west side, they presented a handsome rosewood frame, modestly backed with black velvet, which contained thirty-three gold medals, the awards for many world's expositions, which, by its striking, yet conservative, appearance attracted unusual attention. Physicians wishing a reliable diet for infants, and a pure milk for their table, did not neglect to procure packages of both Nestlé's food and Nestlé's Swiss condensed milk.

One of the handsomest exhibits was that of Reed & Carnrick, who also presented Mr. Cracknell as a sample of what their food can do.

The Jensen, Golden Scale, and Ford Pepsins were represented by Messrs. Ford and Manwaring, whose tests gave the rather singular results that half a grain of pepsin digested more albumen than a grain of the same pepsin. This was due to the larger amount of water used in the first case.

Doliber-Goodale Co. had a large picture of a baby, which seemed to attract the ladies as well as their husbands.

For a firm exhibiting but one article, Platt's stand displayed unusual good taste.

There were scarcely any surgical instruments on exhibition, the owners probably dreading the Newport fogs.

The sable hue predominating at Lambert's exhibit was doubtless due to the lamented death of Mr. Lambert, who was immensely popular with Association physicians.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 23, 1889, to June 29, 1889.

FORWOOD, WILLIAM H., Major and Surgeon. The extension of leave of absence on Surgeon's certificate of disability, by direction of the Secretary of War, granted in S. O. 118, May 22, 1889, from this office, is further extended four months. Par. 14, S. O. 142, A. G. O., Washington, June 20, 1889.

CARSON, J. K., Major and Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. Par. 2, S. O. 65, Headquarters Department of the Columbia.

HOFF, JOHN VAN R., Captain and Assistant-Surgeon. Is relieved from duty at Fort Reno, Ind. Ty., and ordered to Fort Riley, Kan. Par. 6, S. O. 145, A. G. O., Washington, D. C., June 24, 1889.

BACHE, DALLAS, Major and Surgeon. Is relieved from duty at Fort Riley, Kan., and ordered to report to commanding general, Department of the Platte, for duty as Medical Director of that department. Par. 6, S. O. 145, A. G. O. Washington, D. C., June 24, 1889.

WOODRUFF EZRA, Major and Surgeon. Is relieved from temporary duty at Fort Monroe, Va., by direction of the Secretary of War, and will report in person to the commanding officer at Fort Hamilton, N. Y., for duty at that station. Par. 5, S. O. 146, A. G. O., June 25, 1889.

FISHER, WALTER W. R., Captain and Assistant-Surgeon. The extension of leave of absence granted, by direction of the Secretary of War, in S. O. 41, June 12, 1889, Division of the Pacific, is still further extended fifteen days. Par. 8, S. O. 146, A. G. O., Washington, June 25, 1889.

FISHER, WALTER W. R., Captain and Assistant-Surgeon. The leave of absence granted for one month, by S. O. 30, c. s., Department of California, and extended fifteen days by par. 3, S. O. 37, c. s., from these headquarters, is further extended fifteen days. Par 1, S. O. 41, Headquarters, Division of the Pacific, San Francisco, Cal., June 12, 1889.

HARRIS, HENRY S. T., First Lieutenant and Assistant-Surgeon. Is granted leave of absence for two months. Par. 13, S. O. 140, A. G. O., June 18, 1889.

By direction of the Acting Secretary of War the following changes are ordered:

TEN EYCK, BENJ. L., First Lieutenant and Assistant-Surgeon (recently appointed). Ordered to Fort Leavenworth, Kan.

GARDINER, JNO. DE B. W., Captain and Assistant-Surgeon. Relieved from duty at Fort Leavenworth, Kan., and ordered to Fort Reno, Ind. Ty.

WALES, P. G., First Lieutenant and Assistant-Surgeon. Par. 3, S. O. 132, June 8, 1889, A. G. O., is so amended as to direct you to report to Fort Huachuca, Ariz., for duty in place of Presidio of San Francisco, Cal.

WYETH, M. C., Captain and Assistant-Surgeon. Relieved from duty at Fort Huachuca, Ariz., and ordered to Fort McDowell, Ariz.

WOOD, LEONARD, First Lieutenant and Assistant-Surgeon. Relieved from duty at Fort McDowell, Ariz., and ordered to Post of San Francisco, Cal. Par. 2, S. O. 138, A. G. O., June 15, 1889.

TEN EYCK, BENJAMIN L., First Lieutenant and Assistant-Surgeon (recently appointed). Will proceed from New York City to Fort Leavenworth, Kan., by direction of the Acting Secretary of War, and report for duty to the commanding officer of that post. Par. 2, S. O. 138, A. G. O., Washington, D. C., June 15, 1889.

Changes in the Medical Corps of the U. S. Navy for the week ending June 29, 1889.

SIEGFRIED, C. A., Surgeon. Detached from the U. S. S. "Quinnebaug," and wait orders.

CURTIS, L. W., Passed Assistant-Surgeon. Detached from the U. S. S. "Quinnebaug," and wait orders.

SMITH, GEO. T., Assistant-Surgeon. Ordered to the Army and Navy Hospital, Hot Springs, Ark.

The Dietetic Gazette.

PHYSIOLOGY OF DIGESTION—THE NUTRITIVE ORGANIZATION.

By WILLIAM WOOD, M.D.,
Professor in the University of the City of New York.

THE body anatomic is made up of a number of completely organized systems, osseous, nervous, muscular, etc., of which three distinctly contribute to the foremost and decidedly important function of nutrition.

Let us give the three a hasty glance. Turn to an anatomical plate of the alimentary canal, the intestinal system. Though rudest and coarsest it is not the least interesting. A mouth cavity set with teeth, a long gullet, the stomach or chymepouch, the liver with its bitter bile, the large coils of intestines, small and large, all these form the vegetative, earthy portion of man. All this mechanism receives, masticates, digests, liquefies, and unifies crude matters, animal, vegetable, mineral, solid, viscid, liquid, reducing everything to an even paste. This is the system of crude chyme, the system of alimentation, the feeding system.

Take next the plate of lymphatics; that is to say, the absorbent system. The black ground represents the flesh, upon this ground throughout head, neck, trunk, and limbs are seen a million white rootlets. These rootlets which thus are implanted on the flesh are perpetually sucking up juices, drinking, absorbing. They are thickest and attain the maximum upon this intestinal tract. Upon the intestinal system this absorbent system seems to be implanted or to form a continuation. All the rootlets are filled with milky chyle or lymph. The main trunk of this root system is the thoracic duct.

Turn to a third plate, the circulation, the vascular system. By its strange branching it reminds one more than any other part of the anatomy, of the branches of a tree. We see main trunks, lesser trunks; large branches, small branches, shoots, and capillary twigs. From the heart goes the aorta, large arteries, small arteries, capillaries, then small veins, large veins, and so on up to the ascending and descending venæ cavæ.

Into this majestic vital stream the thoracic duct pours its prepared milky fluid. We see plainly how the three are connected together; the lymph or chyle system is implanted on the alimentary or chyme system and empties itself into the blood system. In the intestinal system is crude chyme or soluble food. In the absorbent system milky chyle, liquid or vitalized food. In the circulating system blood, which is organized, vitalized, or plasmic. The first is the crude digestive section, the second is the absorbing section, the third is the plasmic section, with its double process of assimilation and disassimilation.

Poetically, the first is the earthy part of man; a reservoir system. The second is the vital root, and

the third the vital trunk of man. Such a simile is convenient for the time as a mnemonic aid in grasping the whole of this vast and complicated mechanism.

It will be seen that the field and contents of this organization are immense. Three complete systems, alimentary, absorbent, assimilative, each of which covers or comprises, in a way, the whole man. They involve many interesting and complicated apparatuses and nearly five hundred distinct organs.

To see the origin of the mechanism of nutrition, and trace its development, we must look to comparative anatomy. Here we find that the intestinal system, or alimentary canal, in the higher animals consists in its entirety of two sections, eight cavities, and thirty-nine organs. Its two main sections are the "respiratory intestine" and the "digestive intestine," the chief center of the one being the lungs and that of the other the stomach.

The intestinal system, at its simplest, in a fresh water polyp, is a simple pouch with a mouth opening. In the lower worms it consists of a stomach with a mouth and an anus. In ascidians this intestinal tube is differentiated into two sections, the respiratory, or gill, intestine before, and the digestive, or stomach, intestine behind. In the lowest fishes gill arches appearing behind the gill openings in the gill intestine form lip cartilages and a jaw skeleton, and the swimming bladder grows out from the larynx, whilst a liver blind-sac grows from the stomach pouch of the digestive intestine, developing into a compound liver gland.

In the intestinal system of dipneusta, amphibia, etc., the swimming bladder is modified into lungs, the larynx originates from the upper end of the trachea, the urinary bladder grows from the last section of the intestine. In marsupials the primitive mouth and nasal cavity is separated by the horizontal palate roof into food passage and air passage, and the anal urinary cavity, cloaca, is separated by a partition into a uro-genital aperture and a posterior anal aperture. Finally, we arrive at man, where the system reaches its perfection.

In man the eight cavities with their organs are as follows:

1. The mouth cavity, cavum oris, with its mouth opening, lips, jaws, teeth, tongue, bone, salivary glands, palate, and uvula.

2. The nose cavity, cavum nasi, comprising the nose canal, maxillary, frontal, and ethmoidal sinus.

3. The throat cavity, with isthmus, tonsils, pharynx, Eustachian tube.

4. The lung cavity, comprising larynx, trachea, and lungs.

5. The anterior intestine, œsophagus, cardia, stomachus, pylorus.

6. The central intestine, that is, the gall intestine, duodenum; empty intestine, jejunum; and crooked intestine, ilium, together with liver and pancreas.

7. The posterior intestine, colon, cæcum, rectum, anus.

8. The urinary intestine, comprising urinary tube and urinary bladder.

It cannot fail to be remarked that this vast aggregate, the coarsest and most primitive organization in the body, the oldest, according to some anatomists, has little about it that is fine or spiritual, but much that is gross, earthy, and material. These eight yawning cavities, mouth, nose, throat, lungs, stomach, intestine, rectum, bladder, are so many canals and reservoirs of earth, air, and water, sac or pouch reservoirs of pabulum, nourishment, and drainage. They are the foundation and cellar of the human edifice.

The lymphatic and lacteal organs, vasa absorbentia, the absorbent system, consist of countless myriads of little villi, rootlets or suckers, fastened upon the intestines and strewn, at intervals, with certain nodosities or glands. These rootlets unite in a root-like tube, the thoracic duct, which leads up into the circulation. These vasa absorbentia are not limited to the digestive tract, but send their rootlets in the form of lymphatic capillaries and lymphatic lacunæ, through nearly all tissues except brain and bone; and this absorbent system is like a root implanted on the intestines and overgrowing all the rest of the body. The remainder of the system comprises jugular trunk, or root, the subclavian trunk, the bronchial trunk, all emptying into the right lymphatic duct. The lumbar trunk joins with the thoracic.

Lymph and chyle, the white blood, are of the same composition; serum, white corpuscle, fibrine, fatty globules. When entering the great trunks of the system this white blood passes from a soluble food, or pasty chyme, to liquid food, chyle or milk, which by passing through the nodosities or lymphatic glands becomes vitalized milk, or lymph; that is to say, it acquires the white-blood corpuscles which are formed and living elements. If the blood of the sanguine system is called liquid flesh, the fluid of the lymphatic system might be called white blood or liquid white flesh, plasma not yet brought up to the standard. Its clot is thin and pale; it must pass on into the veins and through the lungs and liver and be further purified, further refined and further elaborated, and further built up before it becomes true plasma.

By studying the lymphatic system as a whole we see where the chyle or white blood originates. In normal states the grand supply is from the intestines through the villi, or rootlets, and so through the thoracic duct. In case the normal supply fails, the intestinal reservoirs being empty, then the lacunæ and reticular vessels begin a more serious work, as it were, sucking and drinking up the tissues of the body. Emaciation ensues, noted especially in such diseases as phthisis, severe dyspepsia, etc. In all cases of inanition a man, by his absorbent system, absorbs or drinks his own flesh, literally sucking the life out of himself, the lymphatic system becoming an immense leech, covering the whole surface of the body. Science, as well as observed fact, shows us that starvation is a fearful and terrible process.

To sum up at a glance the whole of this curious white blood or lymph tract: First, its rootlets, the sucker-like villi of the intestines, capillary or thread-like and lacunar or web-like upon the other tissues. Second, the nodosities, lymphatic glands, lymphatic ganglia in which the blood is united, elaborated or vitalized, being given the white blood corpuscles.

Third, the five root trunks, jugular, sub-clavian, bronchial, intestinal, lumbar. Fourth, the two grand trunks emptying into the circulation, on the left the thoracic duct; right, the right lymphatic duct.

The circulatory or assimilative system consists of veins, small and large, with the two main trunks leading to a propelling organ, the heart; then through the trunk arteries, large arteries and small arteries to the capillaries, where the work of building and repairing is constantly going on.

This highly ramified tree, whether we study it from embryology or comparative anatomy, has a history. It is not one of the earliest tissues, for the skin, stomach, kidneys, nerves and muscles have all preceded it. Only the skeletal and the genital systems were formed later. Comparative anatomy shows the vascular system in various stages of completion. For instance, in the lower worms Bryozoa, appearing between the skin covering and the intestinal wall a simple body cavity. In the scolicida appears a long, dorsal vessel above the intestinal tube, a long ventral vessel behind it, the two connected by rings encircling the intestine. In ascidians a portion of the ventral vessel is enlarged to a simple heart pouch. In fishes the heart divides into two chambers, the lymph system appears side by side with the blood system. In the selachii five artery stalks rise from the main chambers of the heart. In amphibians only the right and left aortal arches are developed, whilst in mammalia the heart has four chambers and the left aortal arch alone is developed. We see here a law of decrease in a number of grand trunks and increase in the number of heart chambers.

Turn now to the elaboration of the material, up through this three-fold labyrinth, the vital reservoir system, vital root system, and vital trunk system to reach its final destination in the flesh. The bolus as it leaves the mouth is wetted and masticated; it is still crude food. As it leaves the stomach peptonized, it is soluble food. As it is absorbed by the villi having been emulsified by mixture of bile and pancreatic juice, it is liquid food. After passing the lymphatic glands it is vitalized food. After passing into the veins and through the portal system, it is crude blood plasma, and after passing the lungs it is purified blood plasma.

By the natural miracle of transubstantiation the bread is made flesh. The eggs, bacon or biscuit eaten in the morning before the day is over will be living, walking, talking, writing letters. The change is fearful and wonderful if we simply contemplate it. Natural and admirable, scientific and not less wonderful, if we observe, test, measure, weigh and experiment. This humble mouthful of bread to fulfill the order of its being, to carry out the veritable purpose for which it was created and complete the great metabolic cycle must pass through fifteen processes. The mediæval miracle of transubstantiation was performed "presto" at a blow, the modern scientific miracle of metabolism develops by stages, elaborates little by little, inch by inch, increment by increment. Prehension, mastication, insalivation, deglutition, peptonization, emulsification, fermentation, absorption, vitalization, elaboration, purification, circulation, assimilation, disassimilation, such are the fourteen processes of the foremost of all vital functions.

How may bread become flesh? Follow out this *bouchee de pain* as it plunges down into this vital mælstrom and seek to follow it through all its windings in the thirty feet of intestinal canal through the absorbent system, through the miles of veins, and through miles of arteries.

Food is licked or sucked by the lips, lapped with the tongue, bitten by the teeth, finds itself cut, torn, and ground by incisors, canines, and molars, held fast and mashed up by masseter and buccinator muscles, made moist and slippery by the saliva, moulded and rolled up into a bolus by that extraordinary muscle, the tongue, with its nine complicated movements, and thrown backward, it leaves its first cavity to pass to the second. Deglutition is a complicated and difficult performance involving many muscles, many nerves, and consisting of six distinct acts. Peristaltic action brings the bolus to the stomach, it is deluged with pepsin and hydrochloric acid and churned by a peristaltic and rotary motion through the combined action of longitudinal circular and oblique muscles. Only one portion of the food is dissolved. The nitrogenous or motor portion, fats and starches; the more vegetative portions wait for the next solvent in the duodenum, the bile intestine. The pasty mass of chyme is now again deluged, this time with bile and pancreatine mixed together. The pancreatic juice attacks the starch, exerts a hydrolytic influence, and emulsifies 40 per cent. of the fat, probably the simpler fats. The bile exerts an antiseptic influence, emulsifies nearly 60 per cent. of the fats, probably the more difficult ones. The pancreatic principle, apparently like the salivary principle, operates primarily on the starch or carbohydrates and proteids, and secondarily upon the fat, while the bile attacks directly and strongly the fats or hydrocarbons. Through the two we have a complete sugar transformation and saponification, and the whole is now chyle, a sugary, soapy, egg-white, milky mass, in taste not unlike mother's milk. Four million lacteal rootlets or villi drink this up. The number of human rootlets has been carefully estimated by Kraus. They begin in the duodenum, decline in the jejunum and disappear in the ileum. In the lower intestine, striking fermentative processes go on and strange substances are produced, phenol, skatol, etc., but we will follow the milky fluid into the lymphatic system. Chyle passes into lymphatic glands by the vasa afferentia, and when it comes out by the fewer vasa efferentia, *it is alive* with amœbæ or white blood corpuscles. In the spleen and portal circulation it is farther elaborated, reddened, and strengthened by the red blood corpuscles, iron corpuscles, sent to the lungs it throws off its dark impurities and is vivified with oxygen, and we might find here a fifteenth process vivification, and finally with a hot rush from the propelling left ventricle, all sparkling and quivering and alive it bounds through the narrowing passages to meet the myriad capillaries that are waiting for it. Living brick and mortar it is piled up in unstable molecules in the columns of muscles. As vital cell units these live their little

lives, do their little work. Their function ended, they are dissimilated, disintegrated, pass into the torrent as effete matter and are expelled from the organism, the carboniferous portion through the lungs, the nitrogenous portion through the kidneys. Their two natures as it were divorced, one going to the air, the other to earth. Is not man himself and every animal compounded chemically of this double substance? By carbon the organism lives and grows, by nitrogen it moves.

The three systems, reservoir system, absorption system, and assimilation system, with their fifteen or sixteen processes, form an immense chemical apparatus, and the iatro-chemists were not far wrong when with the iatro-mechanicians they divided the empire of man. The surgeon's field is the exterior or mechanical part of man, the physician's field is the interior, the chemical part of man.

You may say literally that the nutritive or chemical organization comprises the whole of the inside of the organism. We refer to it daily when in popular phase we speak of a man's inside. The man who has big lungs and a big stomach, and a powerful circulation may be said to have a powerful nutritive organization.

To the stomach the organism looks for its food, to the lungs for its fire. The nutritive organization is of all the four most costly to support, yet it must be supported. Nine-tenths of all one's expenses go for the supply of stomach and lungs. Hunger, thirst, suffocation and cold ensue when the wants of the nutritive organization are not attended to. It is the system of vital importance, the veritably vital organization, and to supply its wants all the agriculturists, three-fourths of the manufacturers and half the traders of this world are at work. Food and drink and fuel cost something, houses and clothes supply wants, and from these vital wants or necessities men work to accumulate food, drink, fuel, clothes and shelter. Comforts and luxuries are delightful, pictures and books are edifying, but the necessities of this world are what rule it. From the decrees of hunger and cold there is no appeal, and the general belief is that property, if not the highest thing, is at least before all else a good thing. Lands and houses, much cattle, and heaps of gold and silver, what are they? Necessities, tissue formers and heat producers, nothing else. They all go first and foremost to the support of that tyrant inside of a man, the nutritive organization.

THIS is the third summer in which I have been using the sulpho-carbolate of zinc as a remedy in summer complaint. As yet I have no reason to alter the opinion I formed two years ago: that this is the safest and most effectual remedy at our command for producing intestinal asepsis. In simple diarrhœa, the alkaline syrup of rhubarb, with the addition of a little tincture of hydrastis (a drachm to the ounce of syrup), answers every purpose; but if this does not promptly cure, or if the stools continue to be offensive, or if the case looks at all serious, I order at once the sulpho-carbolate, in doses of one-half to two grains every two hours, in powder with a little bismuth.—*Waugh.*

THE FEEDING OF PUERPERAL CONVALESCENTS.

By CHARLES MEIGS WILSON. M.D.,

Physician in charge of the Philadelphia Lying-in Charity, etc.

NO dietary regimen for convalescents has undergone in the last few years a greater change than that for women resting after the fatigue of their lying-in. The old-fashioned idea, until recently taught, and even yet generally followed and accepted by the mass of the profession at a distance from centers of medical thought and progress, that women undergoing their puerperal convalescence should be fed upon a skimp diet, is happily for the credit of the profession and the welfare of patients rapidly becoming a thing of the past. The notion so prevalent thirty or forty years ago, that to give a puerperal convalescent a good wholesome, easily digested and easily assimilated diet was a dangerous procedure, has gone forever, and given place to a proper dietary regimen, based upon the clinical observation of what is needed to best restore the whole economy to its regular hygienic functional activity, to restore the vital forces of the patient, exhausted or overtaxed by the process of parturition, to enable her to furnish the proper amount of nutritive material to supply the wants of her own economy, and to furnish a proper pabulum for the sustenance of her offspring. Aside from the first requisite, the proper sustenance of the mother herself, all dietary regulations should also have in view the fact that lactation must be promptly and efficiently established, and that, too, in such manner that it shall entail upon the mother the least physiological strain and loss of strength. The foregoing facts are, of course, patent to every observing man, and with their acceptance, the practitioner is at once faced with the two propositions—first, what then is the proper diet for a lying-in woman, and second, how must it be modified to best support and nourish her in any accident or emergency which may occur during her puerperium? With reference to the first proposition, having started out with the acceptance of the fact that the woman needs easily digested and easily assimilated food, in quantity sufficient to furnish a proper pabulum for her own and her offspring's nourishment, and by the term proper, I mean a sufficiency of quantity as well as a proper standard of quality, what then shall be a proper bill of fare for a woman going through a normal convalescence following a labor? In private as well as in hospital practice it has been my habit to carefully instruct my nurse after every case of labor, as regards the diet of the patient, telling her as soon as the patient is properly cleansed, and the room put in order, to bring the patient a cup of hot tea or coffee, well diluted with milk, and a small piece of softened water toast or a small water cracker. If the patient has a liking for cocoa or chocolate, all the better, and indeed in the Lying-in Charity this is a favorite article in use for primary alimentation. If the patient prefer it she may have instead, a glass of milk, or milk slightly diluted with water, charged with carbonic acid gas. This may be given hot or cold, but as a rule warm or hot drinks are most acceptable to

the patient, better borne by the stomach, and have the additional advantage of stimulating the uterus to contract, thus insuring prompt primary involution of that viscus, and lessening the likelihood of secondary post-partum hemorrhage. After the patient has had an interval of repose and rest, and upon her expressing a desire for food, the nurse is directed to give her a cup of animal broth, beef, chicken or mutton tea, to which has been added some rice or barley, the latter so long immersed and so well boiled in the soup that the grains are disintegrated. Then at the next meal time the patient may have a soft cooked egg or some milk-toast made out of stale bread; in addition she is given from time to time a glass of milk. No form of easily digested and nutritious food for which the patient may have a desire, provided it be of the semi-solid variety, however should be interdicted. And thus the patient should be fed until the bowels are moved. This, it is my habit to have take place at the end of forty-eight hours.

In the Lying-in Charity this is accomplished by giving one or two drachms of compound licorice powder in a half tumbler of water on the evening of the second day, followed, should it fail to move the bowels, by a rectal enema of two ounces of glycerin on the morning of the third day. I know of no better plan to pursue in private practice, provided the patient will submit to it. It makes no difference what laxative is used, provided it is mild in its action and non-drastic. The object desired is to gently move the bowels. Once an evacuation from the bowels has taken place the patient is allowed to use her own choice in the matter of food, except that all indigestible and fatty foods are interdicted, as well as the leguminous vegetables—peas, beans, potatoes, and such like. On the contrary, she is urged to eat of green vegetables—salad, asparagus, and so forth. Meat is given for the morning and noon meal, if the patient desire it, but the evening meal is always a light one and of a simple character. Midway between each meal, and at bedtime, the patient is given a glass of milk to which has been added a half an ounce of lime water. It is essential to see that the bowels are opened at least once in every forty-eight hours. This is best accomplished by getting the patient to take a little stewed fruit in the way of dessert, as stewed prunes or prunelles, or an orange before breakfast. If these simple means fail the licorice powder and glycerin enema should be repeated. The foregoing directions as regard the diet of the puerperal convalescent applies, of course, only to those whose convalescence is a normal one—devoid of pyrexia—and uncomplicated by sepsis or any other accident of the puerperium. Now, as regards our second proposition. How shall this dietary regimen be modified by any of the accidents of parturition or of the puerperal state? In reply, it is necessary to state that each accident of labor and every deviation from a normal puerperal convalescence needs more or less change or modification of the diet. Let us consider first the conditions of exhaustion following a tedious or protracted labor. Here the great thing is to speedily restore the vital forces, and do it in such a way that the little strength or vitality left the patient shall be taxed in the process of digestion and assimilation as little as possible. To meet these indications the patient should be put almost exclusively upon a milk diet, because that food is most easily assimilated and digested and quickly turned in the economy into life-giving strength. Under these circumstances also, small quantities of alcohol are indicated; as drachm or two of whiskey or brandy every two or three hours. This diet may be varied by giving occasionally a small quantity of Valentine's fluid extract of beef, properly diluted with water, or some concentrated animal broth. Where profuse post-partum hemorrhage has taken place, the first need is stimulation—a cup of hot coffee—followed at short intervals with as much milk, diluted with lime water and given in small quantities, as the patient will take. Mild stimulation is also needed. One of the most acceptable agents to use for this purpose is champagne, a dry brand, or whiskey or brandy diluted with carbonated effervescing water. No form of food more quickly restores the volume of blood, and makes up for the blood lost, in post-partum hemorrhage than milk. Where labor has been complicated by uræmia, eclampsia, or albuminuria, and when, of course, the circulation is loaded with retained urea and teems with excrementitious matter, the patient wants food to support her through her ordeal of complicated convalescence, whose digestion will yield but little urea. What better food have we for this purpose than milk? Under these circumstances, also, all forms of meat should be excluded from the patient's diet. It stands without need of defence that wherever pyrexia supervenes the patient should have an absolutely liquid diet. Should the patient have diabetes, a diabetic diet should be employed, from which all articles of food containing sugar and starch should be excluded. Acute illness developing during puerperal convalescence requires no different diet from that which would be employed had the disease appeared other than at the puerperal period. Where galactocele or galactorrhœa—in other words, hypersecretion of milk—occurs, the patient should be placed on a dry diet, *i. e.*, one in which the liquids are excluded as far as possible. On the other hand, where the mammary glands fail to properly perform their functions and secrete a sufficient supply of milk to afford nutritive pabulum for the child, the diet should be, as far as possible, liquid in character and rich in the elements of nutrition; hence, of course, we would give milk, as much as the patient can take, and concentrated animal broths. For this purpose I have frequently used, with great satisfaction, strong gruels made of Mellin's food. Where the stomach has been irritable, or non-tolerant of food, I have met with the best success in feeding my patients by using peptonized sterilized milk, sterilized after the method of Prof. Soxhlet, and peptonized with some good pepsin. The directions herein given for the alimentation of puerperal convalescents are based upon the clinical observation and experience of more than a thousand cases of labor and puerperal convalescence, the majority of which occurred in the Philadelphia Lying-in Charity, where every possible

means was afforded for observation, and where faithful records of all cases were accurately kept. They are also based upon a series of interesting experiments in which the amount of milk secreted and the amount of urea excreted were carefully noted, as compared with the kind and amount of food given.

121 South Seventeenth St.

DIETETIC TREATMENT OF PATIENTS AFTER ABDOMINAL OPERATIONS.

By E. E. MONTGOMERY, M.D.,
Professor of Gynecology in the Medico-Chirurgical College, and Obstetrician to the Philadelphia Hospital.

THE question of the food and drink of patients having undergone abdominal operations is one of obvious importance, often influencing seriously the subsequent result.

The character and quantity of food will depend largely upon the condition of the patient, and the gravity of the operation. Generally, in oöphorectomy and uncomplicated ovariotomy, the patient may be permitted to resume the ordinary diet after the first forty-eight hours. The early administration of nourishment in such cases is not urgent; indeed, from the effect of the anæsthetic, and the influence upon the reflex nervous system produced by the imprisoned nerves of the pedicle, no nourishment through the stomach would be likely to be retained. Nausea and vomiting are generally present, their absence the exception. The greatest cause of distress, however, is the intense thirst which, if anything, is intensified by the use of ice and ice water. Much relief can be given by the use of enemata of warm water, injecting half a pint to a pint slowly. In continued nausea and vomiting, particularly where the patient is retching and making efforts to vomit, the administration of hot water, soda water, or weak tea, without sugar or milk, will even if ejected give relief by diluting and washing out the irritating material of the stomach.

Milk is not a satisfactory diet in operative cases of this class, because of the firm curd which it produces. It should be given only after being peptonized, or in the form of the koumiss or kiappyr preparations.

From an extended experience, I have been very favorably impressed with the beef preparation, known as Bovinine, as a means of nourishment in the early stage of the convalescence. It affords nourishment in a highly concentrated form, which is readily retained and assimilated.

In simple cases it is unnecessary to continue this diet exclusively after the first forty-eight hours. The diet should be nutritious, exercising care to avoid indigestion and overfeeding.

In the more grave operations we may be confronted by the necessity for prompt and early support. In such cases, and in those affected by obstinate and prolonged vomiting, feeding by the rectum affords an opportunity for temporary support and stimulation. As no digestion takes place in the lower bowel, and its absorption is limited, it is important that the food so used should be that which is most readily assimilated. There is a great difference in the retentive power of the recta; some will readily retain a pint of fluid slowly injected; in others it is necessary to give but small quantities at a time. The first class may be fed entirely upon liquids, while in the latter more concentrated preparations are preferable. A combination of bovinine ʒj–ʒiv and peptonized milk ʒiv, given every three hours, serves a useful purpose. To this may be added, as the condition requires, whisky or brandy as stimulants.

The bowel should be thoroughly washed out once daily with an enema of warm water, by which the unabsorbed material is removed.

Itis important that the injections should be carried, high up, in order to come in contact with as extensive an absorbing surface as possible.

As soon as the condition of the patient will permit the rectal feeding should be supplemented by nourishment through the stomach. This should be given in small quantities, and frequently repeated.

In no class of cases is the character of nourishment and method of administration of more importance than in those in which the alimentary canal itself has been the seat of operation.

For the first week the feeding should be mainly by the rectum, and when food is begun by the mouth it should be given in small quantities, and frequently repeated. Particular care should be exercised to select only food in which there is the smallest proportion of waste.

The concentrated beef extracts, the peptone preparations, peptonized milk, broth and gruels, and such fermented articles as koumiss and kiappyr afford sufficient variety to prevent liquid foods becoming monotonous.

The development of profound shock, obstinate and prolonged vomiting, tympanites, peritonitis, and other complications, should be combatted by proper therapeutic treatment, but as this paper is directed to the dietetic management alone, their consideration here would be out of place.

HYDRIODIC ACID.

By JOHN V. SHOEMAKER, A.M., M.D.,
PHILADELPHIA.

IF any alterative is more in demand than the iodides, it would puzzle therapeutists to agree upon its name. Many obscure deviations from health exist, amounting not always to pronounced disease which will not give way to simple tonics or to depurants of the purgative order. These maladies are the bane and torment of a busy doctor, and many times he gets them out of his list by the use of iodides. Then again, when well-defined cases of scrofula and syphilis are under our care, the value of a good alterative is preëminently a question of moment. Unfortunately, the iodides in large or long-continued doses have a tendency in many instances to inaugurate stomach disorders, and yet the absolute need of the remedy is apparent. What then shall we do? We can have recourse to hydriodic acid. For years this agent was officinal in the Dispensatory, but it was dropped because of its unstable character, which made it not only unpleasant, but unsafe to administer. For almost ten years the acid was not obtainable, until in

1878, when Mr. R. W. Gardner, of New York, introduced the agent in the form of a sirup, which the best tests have shown to be unalterable by any ordinary exposure in the sick-room, unless in hot weather, when, of course, it should be excluded from either extreme light or heat. Sufficient time has now elapsed to demonstrate that the claims made for the sirup are well founded, and that it replaces the salts of soda and potassa in an entirely satisfactory manner. An important addition in the form of the sirup of hydriodic acid has therefore been made to current therapeutics. By the use of this sirup we obtain, in a palatable form, iodine in its most effective state. Mr. Gardner has shown that:

"When not decomposed, hydriodic acid is of a light-yellowish color, is perfectly non-irritant, gratefully acid to the taste, and rendered still more acceptable if combined, as in this preparation, with sugar.

"In chemical composition it consists of one equivalent each of iodine and hydrogen (HI). As the equivalent of iodine is 127, and that of hydrogen 1, it follows that the proportion of hydrogen present as compared to iodine is less than 1 per cent. (78–100 of 1 per cent.). Absolute hydriodic acid is, therefore, nearly pure iodine. It affords the most natural and effective means of assimilating iodine, as the hydrogen with which it is combined is one of the largest elementary constituents of the body. The combination renders iodine more assimilable, therefore, because in physiological harmony, while it is medicinally more active, and deprived of its objectionable irritant properties, and changed from a most disagreeable to one of the pleasantest of remedies."

One fluidounce of this sirup contains 6.66 grains of iodine converted into hydriodic acid. Its action will be found more efficient in equivalent doses than iodide of potassium, while it produces none of the unpleasant effects of the latter, such as loss of appetite, soreness in the fauces, nausea, etc. Physicians who use iodide of potassium largely will appreciate this, because it is more active than iodide of potassium, and should be given in smaller relative doses, thus not interfering with digestion.

Its effect upon mucous surfaces is more marked than with other forms of iodine, while it is effective in smaller relative proportions, and when required, it is so free from irritant action that it may be given to the youngest infant.

Our chemist just quoted further adds that hydriodic acid has a characteristic subacid taste, and if the sirup contains about 6.66–100 grains in one fluidounce, it will taste like lemon sirup, or lemonade. Consumers of the sirup can be guided as to any deleterious change in it by noting the color. When decomposition has occurred in sirup of hydriodic acid, it becomes first red and finally black. This is owing to the very feeble chemical affinity existing between its elements, and is caused by the gradual oxidation of the combined hydrogen into water (HO) and the consequent freeing of iodine, which passes at once into solution in the remaining hydriodic acid.

In this condition it is unfit for medical use, because the irritant action of free iodine is again restored.

It will be seen that this change is inherent, though it may be delayed. After this change has commenced, however, it is progressive, and the preparation cannot be restored to its former condition.

The best method of preventing this change is to keep the sirup in as cold a situation as possible, in a refrigerator if convenient, during warm weather, and carefully excluded from air by keeping it well corked.

The sirup of hydriodic acid is especially serviceable in asthma, hay fever, acute and chronic rheumatism, chronic bronchitis, and in many chronic congestions of the mucous tract. Probably the greatest value to the practitioner of sirup of hydriodic acid will come from its employment in syphilis, particularly in the latter stages. The stomach is often rebellious at this time, for it has most likely been surfeited with mercury. Many cases drag along under iodine because not enough of it can be borne, and mercurials frequently are not only useless, but at times injurious. Instances such as those related bear admirably large doses of sirup of hydriodic acid. Some cases have come under my observation in which the patients were at a standstill, who at once brightened up and rapidly improved under the use of the sirup of hydriodic acid. If thought desirable, the biniodide of mercury (the red salt) can be combined with the sirup, but the protiodide cannot be used at the same time, because it (the green salt) would be converted into the former salt, and unless care was taken the unexpected activity of the sirup thus prepared would exceed the prescriber's expectations, and possibly injure the patient. In syphilis the sirup can be pushed, if needed, until the characteristic saturation is evident, or when the metallic taste becomes pronounced and we know that iodism is near at hand. It is advisable, however, not to carry the administration so far.

In rheumatism the sirup may substitute the alkalies and may cut acute attacks short sooner than the ordinary drugs that are usually prescribed. It is certainly a useful article in chronic muscular rheumatism. It has done good service in my hands in sciatica. It may be administered during acute rheumatic attacks without reference to the fever, and in moderate doses, say a teaspoonful or two every two hours. Of course, it will not act promptly and effectually in all cases, for rheumatism is notoriously fickle as related to curative agents. In bronchial disorders small and frequently repeated doses are better than large ones. It may be administered in this latter affection in from twenty to thirty drops every two hours. The sirup has been recommended in chronic arsenical poisoning, several cures being noted. In lead poisoning it has also been serviceable. In obesity the steady administration of the sirup of hydriodic acid with suitable regimen has a very happy effect. We are not too well supplied with agents of repute in this disagreeable complaint, hence a note on this point in reference to its use in this respect is of utility.

Many skin diseases are benefited by the sirup of hydriodic acid. In connection with cod-liver oil it is valuable in some varieties of eczema, particularly in children. It is especially efficacious in the form known as scald head, which is often so obstinate and

unyielding to many remedies. Scrofulous persons (those predisposed to glandular troubles) receive decided benefit from its use. The red-eyed children, those having recurrent granular lids, with repeated attacks of mild conjunctivitis, derive great relief from sirup of hydriodic acid. A case of amyloid liver with fatty heart, in the practice of Dr. F. A. Burrall, of New York, was notably aided by the sirup of hydriodic acid, and he indorses it in glandular troubles generally. Dr. Blackwood, of Philadelphia, has employed it largely in his practice, and reports cases of exophthalmic goitre, lumbago, and uterine catarrhs, which were cured by the sirup. It is desirable that hydriodic acid should be given by itself; inasmuch as it is very susceptible to chemical action, combinations with other remedies might act injuriously upon it. Metals and alkalies are incompatibles, so also are oxidizing agents, as, for instance, acids, permanganate and chlorate of potassium. These would form iodic acid, which would be highly injurious to the patient. If intolerance becomes apparent, as occurs with all really active medicines, after a more or less extended use, the sirup should be dropped for a week or ten days, when most likely the stomach will have recovered its tone and it may again be administered. Unlike many remedies which, when once objected to in this way, are never likely to be good again, the sirup is just as palatable and equally efficient when taken up after a vacation (so to speak) as when first given, which is an important characteristic of this remedy. Although sirup of hydriodic acid is used by many practitioners, we call attention to it believing that a wider knowledge of it is desirable, and feeling certain that a careful trial by physicians at large will add to their armamentarium an important remedial agent, and that they will learn to appreciate its value as we have, by its employment in a wide circle of disease for many years.

FOOD IN THE TREATMENT OF PULMONARY CONSUMPTION.

(Abstract of a paper read before the American Medical Association.)

By SOLOMON SOLIS-COHEN, M.D.,
PHILADELPHIA.

THOUGH this paper is therapeutic, yet as therapeusis must be founded on sound pathology, it is necessary to state that the morbid physiology of the disease, and not its bacteriology, is considered the fundamental indication. In deference to prevailing views, tuberculosis may for the present be granted to be the history of the growth, life, and activity of a bacillus. But for rational treatment we must revert to the views of Niemeyer, who said that the danger of phthisis is tuberculosis; or to those of Rush, who declared that tubercle and other anatomical lesions were "the effect, not the cause of pulmonary consumption;" and recognize the disease we have to combat, not in epiphenomena of possible microbic origin, but in the consumption, the aberration of nutrition, which precedes the entrance of the microbe. Consumption is a disease of nutrition, whose exact mechanism is as yet unknown, though the results of prolonged observation justify us in considering heredity, unhygienic surroundings, and, in general, those influences called "depressing," as among its remote or proximate causes; the pulmonary form being further dependent upon errors in respiration, whether of the substances respired or of the performance of the act.

Thus we dismiss as futile, microbicidal treatment; and recognize ptomaines of bacillary origin only as giving rise to intercurrent symptoms which may call for antidotal or symptomatic treatment. Fixing attention upon the malnutrition, which is not a mere "predisposition" to succumb to a bacillus, but the essence of the whole morbid process, we combat it by direct measures, hygienic and medicinal; the latter secondary, the former all important. Chief among hygienic measures is food. Food consists not alone of meat and drink, but also of air. Full respiratory diet is necessary to the utilization of alimentary diet. As in diabetes, so in phthisis, there is imperfect metabolism of carbohydrates. Experience shows a nitrogenous dietary to be best. Debove has shown that consumptives can assimilate a quantity of food far in excess of the needs of the healthy organism. This excessive quantity should be supplied; though resort to the stomach-tube, as in Debove's experiments, can be reserved for special cases.

Meat, principally beef, with milk, fish, eggs, leguminous vegetables and greens should form the bulk of the dietary; with the addition of fat, in large quantities, in the form of cream, butter, oil dressing for salads, or, if necessary, cod-liver oil or oleaginous inunctions. Alcohol is a food in consumption. It should be combined with malt, milk, glycerin, or cod-liver oil. Not more than three, at most four, hours, except during sleep, should be allowed to elapse without taking food. Milk punch on going to bed, and a glass of wine or spirits with liquid peptonoids in case of waking during the night, are strongly urged. Hot water before meals, lavage, if necessary, to prepare the alimentary tract for the digestion and absorption of increased food, and the free drinking of water to wash out waste products are essential to success. Predigested foods may be employed with great benefit, especially peptonized milk and beef peptonoids. In case gavage is resorted to, they should be used almost exclusively. Gavage is best preceded by lavage with an alkaline solution and chloroform water.

Proper alimentary diet being secured through overfeeding, and the digestive tract and its annex being kept in good condition, proper respiratory diet must be supplied. Open air life, exercise on horseback or bicycle, voluntary respiratory gymnastics, may suffice when the patient is still strong enough. In the majority of cases there must be some artificial aid. The inhalation of compressed air, with or without expiration into rarefied air is the best means. Apparatus should be simple and cheap, so that the patient can use it at home. The principles laid down by Waldenburg are the correct ones. Cohen's apparatus consists of a bellows and a small gasometer, modelled upon Waldenburg's. Its advantages are cheapness, simplicity, and small size, fitting it for home use. After patients are sufficiently advanced

towards recovery, the pneumatic resistance valves of the author, a still more convenient and very cheap pocket apparatus (costing about $5), may be used. It may be used in the first instance with strong patients. It is also useful as a prophylactic measure with ill-developed children. It gives the effects of breathing against pressure, *i. e.*, into compressed air or out of rarefied air.

The effects of pneumatic measures are to increase the volume of respired air, open up unused air cells, facilitate expulsion of pathological products, increase gaseous exchange, facilitate absorption of oxygen by the hæmoglobin, while at the same time the volume of blood and the activity of circulation in the lungs is increased, bringing more corpuscles into contact with the increased volume of oxygen. Penetration of blood into the tissues, tissue respiration, and production of lymph are also increased. Thus local and general nutrition are powerfully stimulated, and an improved respiratory habit and increased respiratory and circulatory power are gained. The products of digestion are properly oxidized and utilized, immature tissue is destroyed and expelled. The promotion of sleep is one of the most marked effects.

The physician thus puts them, by altering his patients' environment in the manner described, into a condition where natural powers complete the cure, and bacilli need not be feared. Illustrative cases were cited, and the conclusion reached that the proper treatment of consumption is not microbicide, but nutritive.

GLYCERITUM PEPSINI VITULINI:

(GLYCERITE OF CALF-PEPSIN.)

A FORM OF DIGESTIVE FERMENT ESPECIALLY ADAPTED TO THE TREATMENT OF THE CONDITION OF APEPSIA IN YOUNG INFANTS.

(A communication presented to the Committee on Dietetics of the American Medical Association, at the Fortieth Annual Session, held at Newport, R. I., June 25, 1889.)

By FRANK WOODBURY, A.M., M.D.
Professor of Clinical Medicine in the Medico-Chirurgical College of Philadelphia, Fellow of the College of Physicians, Member of the Pathological Society, etc.

AFTER the introduction of pepsin into medical practice by Corvisart, about 1854, it gradually grew in favor with the profession, until now it may be regarded as the acknowledged and almost indispensable remedy in the treatment of cases of slow and imperfect digestion. In fact it appears to be the rational means for relief where the symptoms are caused by a deficiency of digestive power in the gastric juice, whether this occur as the result of inherited weakness or of some organic or systemic disease.

Under the stimulus of an ever-increasing demand, the processes of manufacture have greatly improved, until at the present time a substance possessing high digestive power, representing the active principle of the gastric juice, is a well-known commercial article. Having gained an established position as a remedy, the Committee on Revision of the United States Pharmacopœia, in 1880, finally admitted two preparations of pepsin into the Pharmacopœia, and prescribed a standard of digestive strength and the tests by which this can be determined. Both chemical test and clinical experience have shown that there is great diversity in the digestive value of commercial pepsins. This is not only admitted by the manufacturers of this article, but they also publish analyses by competent chemists demonstrating such variation; each being peculiar, however, in proving that the pepsin made by every individual advertiser is superior to that made by all others. The only explanation we can suggest for this remarkable discrepancy is that pepsin in the usual form (in powder or scales) is most active when recently made; or, in other words, in the dry state it more or less quickly loses its digestive power. In truth it has been found, by actual investigation, that the most efficient means of retaining this peculiar power is to preserve the substance in the form of solution; and of all the various menstrua proposed and tried, glycerin seems to be by far the best. As has been conclusively shown by Scheffer, of Louisville, there is an incompatibility between alcohol and pepsin, so that almost all the digestive activity is lost by using this as a vehicle. Therefore, all the various wines and elixirs of pepsin are necessarily weak in their digestive action, and, indeed, most of them are not only without such action at all but they also harden albumen and make it less digestible. As digestion is essentially a process of hydration, alcohol, by dehydrating the albumen, to this extent actually hinders instead of assisting the stomach in its work.

It is to the celebrated philosopher Spallanzani that we owe our knowledge of the fact that the digestive power of the gastric juice resides in a certain organic principle, which was subsequently separated, in an impure state, by the great physiologist Schwann, and named by him "pepsine." Payen afterwards suggested the title "gasterase" as being more appropriate; but it was never accepted by the profession. Pure pepsin was first obtained by Wasmann, by a process which was afterwards adopted on a large scale by Boudault in preparing the "pepsine Boudault," in which the pepsin was combined with starch so that it could be dispensed in the form of a dry powder. Scheffer subsequently suggested milk-sugar as a better vehicle, and this has been adopted in the officinal preparation, pepsinum saccharatum. Although the powder has some advantage for dispensing, Scheffer and all other authorities on this subject agree in preferring the liquid form, which is more active and more permanent.

A curious fact noted by Senebier, the French translator of Spallanzani's work,[1] was that although the active principle of the gastric juice seems to be identical in different species of birds, quadrupeds and men, yet it differs somewhat in its digestive properties in different animals. For instance, the gastric juice of dogs digests bone, and in birds that do not vomit, like the heron, the same fact is noted; while in other birds, like the crow, which regurgitate bones and indigestible parts of the food, the gastric juice is less powerful and will not dissolve bone. In other words,

[1] Expériences sur la Digestion de l'Homme et de Différentes Espèces d'Animaux: par l'Abbé Spallanzani. Avec des Considérations par Jean Senebier. Genève. MDCCLXXXIII.

there appears to be a natural relation existing between the ordinary food of an animal and the quality of its gastric juice. This is a suggestive fact that might be utilized in medicine. For example, although our national Pharmacopœa only recognizes that derived from the hog, foreign Pharmacopœias also admit pepsins obtained from the fresh and healthy stomachs of the sheep or the calf. The reason why hog-pepsin is principally used in this country is that Scheffer found that it is the most active, and, perhaps, also because of its cheapness. From the habits of feeding of some men, it may also be supposed to be the most appropriate artificial digestant to be introduced into their stomachs. In very young infants, however, the case is different. Here the pepsin prepared from the stomach of the sucking calf would seem most suitable. This seems especially appropriate where the child must be fed upon cow's milk, as so many of them are. Indeed, the death of a large proportion of bottle-fed children is directly attributable to the fact that their digestion is not equal to the task of converting the casein of cow's milk into soluble peptones. Moreover, the milk-curdling principle in the gastric juice of the calf may be reasonably supposed to differ notably from that of either the sheep (or Boudault's pepsin) or the hog (ordinary pepsin), and the result of its action upon milk to be more compatible with the subsequent task of peptonizing the coagulum thus formed, because this is part of its physiological action. It is well known that rennet-wine has been used with some benefit in the treatment of defective digestion in infants, but from the fact that pepsin is almost insoluble in wine, it can have very little power of directly aiding digestion. I have recently, with the kind assistance of Mr. W. H. Llewellyn, one of the principal pharmacists of Philadelphia, had some experiments made with calf-pepsin, extracted in the ordinary manner from the fresh stomachs of young and healthy calves with the aid of glycerin, and dispensed in the form of solution. From the moderate experience I have had with it, I have been much pleased with its effects in appropriate cases. It is pleasant, easy of administration, and appears to keep its powers well. The introduction of a small amount of the lacto-phosphate of lime was decided upon in order to ensure a slightly acid reaction, and because a small quantity of calcium phosphate is a desirable addition to the diet of children reared upon artificial food.

It has seemed to me more natural to add the digestive principle after the milk has reached the stomach, rather than to peptonize the milk previously, although this can readily be done if desired, and in the case of older children and invalids a very agreeable article of diet may be made in this way.

In conclusion, there is an important question with regard to the administration of hog-pepsin to young infants, especially in summer, when there is a tendency to diarrhœa; a question which has often occurred to me, and yet I have never seen it referred to. The tendency of swine to suffer with attacks of cholera is well known. Now, with our present knowledge of the relation of diarrhœal disorders to bacteria, the question is pertinent, "Are the precautions adopted usually by the manufacturers of pepsin sufficient to insure against possible contamination with pathogenic microörganisms?" The natural result of administering a pepsin product thus contaminated to an infant already suffering with digestive disorder should make us hesitate before prescribing, and lead us to adopt every precaution in order to secure for our patient a pure and carefully made pepsin. I declare very positively that an artificial digestant which has an offensive putrefactive odor bears upon it, for me, the seal of its own condemnation. Therefore, when I have occasion to administer hog-pepsin either to children or adults, I prefer to order preparations as free as possible from peptones, such as the glyceritum pepsini or pepsinum purum,[1] which do not offend taste or smell and possess a high digestive power.

218 SOUTH SIXTEENTH STREET, PHILADELPHIA.

THE PROBLEM OF INFANT FEEDING.

INTESTINAL DISEASES OF CHILDREN AND CHOLERA INFANTUM.

(In the First Session of the Section of Diseases of Children of the American Medical Association, June 25, 1889.)

By I. N. LOVE, M.D.,
ST. LOUIS.

MR. PRESIDENT: Under proper conditions, the period of growth being antagonistic to decay, man in the infantile state should rarely be the subject of disease.

It is a proposition which will not be questioned, that the great majority of diseases of early life are closely related to interference with and interruptions of nutrition.

The problem of infant feeding has been before the profession prominently for many years, and I feel safe in saying that we are probably nearer its solution now than at any previous time. It goes without saying, that the first month is the most important period of the babe's nutrition, and the principle that they are most apt to go right who start right.

No one will deny that on general principles the proper food for the infant is that furnished in the laboratory of its own mother's breasts; the exceptions prove the rule that they should be provided for with a substitute either from some other mother's breasts or a food which will, as nearly as possible, approximate it.

The most important thought which should be borne in mind in considering the maternal milk is the fact of its perfect sterilization, and in this fact have we the key to the situation.

Through the efforts of Escherich, Forster, Harrington, Meigs, Jacobi, Rotch, Vaughn, Booker, and other delvers in the laboratory and clinical observers, we have been given the cue furnished by dame nature, and should now be able to read the lines which follow readily.

If the conditions will permit, I think that the best substitute for the mother's milk, next to the healthy wet nurse, is a healthy, well-fed, well-cared-for goat or cow; the milk of both these animals, although

[1] See article "About Pepsin" in Philadelphia Medical Times, vol, xix. p. 412, by writer.

not identical in composition with the human milk, possesses the virtue of sterility.

Many things have to be considered in the selection of a substitute for the mother's milk.

I think we should use every effort to secure the nursing of the child upon the part of the mother.

Among the laboring classes the mother is usually able to suckle her young. It is among the upper ten thousand that we find the "poor milkers."

Seventy-five per cent. of my private practice is among the better social class, and in justice to womanhood and maternal instinct, I will say that 90 per cent. of the inability to properly nurse their offspring is due to physical weakness, and not moral turpitude upon the part of the mother.

I am inclined to think, however, that the profession has not been sufficiently alive to the fact that by proper effort, moral, hygienic and medical, the natural nourishment could more frequently be secured.

When it comes to the recommending of a wet nurse, many things are to be considered. First of all, can our patients afford the cost?

Then, again, wet nurses are subject to diseases, such as syphilis, etc., that do not affect cows and goats.

In addition, the wet nurse may be accessible, physically healthy, but so constituted mentally as to be an objectionable member of our family, or her moral character may be such as to make her more objectionable than a leper.

The best way to determine this question is to bring it home to one's self. I recall an experience in my own family—a danger which my little daughter of seven would have been exposed to, by contact with a moral leper, recommended to us as a healthy wet nurse for our infant boy. Better far for the latter to have been wafted to the angels than for our first born to have breathed the same air for a day with the moral monster in the shape of a wet nurse.

For practical purposes the suggestion furnished us by our grandmothers' empirical practice in years gone by (the boiling of the milk in digestive disturbances), is sufficient.

I prefer the plan favored by Rotch in Keating's "Cyclopædia," that of putting the milk in convenient-sized bottles and steaming it for twenty minutes. But whether the milk be steamed or boiled we accomplish the destruction of all putrefactive bacteria and disease germs, as well as the tyrotoxicon and other ptomaines produced by them.

A temperature of 180° F. is sufficient to accomplish this, and in as much as steaming at this temperature does not affect the taste or the accomplishment of the coagulation of an amount of albumen and the throwing to the surface of a certain amount of the fat in the form of a decided scum as does boiling it, it is preferable.

After steaming it the receptacle should be hermetically sealed, and the "Mason fruit jar" for preserving purposes is an admirable convenience for this purpose. The particular place where the milk is kept is then not so important, though the ice chest, refrigerator, or cellar, country well, or spring house should be scrupulously guarded from dirt, and be well ventilated.

Many conditions arise where we need the help of artificial digestion, and we lean not upon a broken reed when we call it into service.

The profession is under great obligations to organized capital and the various manufacturers who have concentrated their efforts upon artificial foods for infants. Many cases arise where these so-called commercial foods are of great value to us.

Babies are like adults in that each one is a law unto itself. What is meat for one is poison for another.

Among artificial foods, Mellin's has often served me well, as also has Carnrick's.

Many cases come to us to which no form of milk can be given. With such I have found Bush's bovinine of great value.

I have no patience with the dilettanteism and the Miss-Nancy-ism which would preclude a physician prescribing or specifying a reliable manufacturer's product, whether it be a drug or a food.

The second topic presented in this session, "the intestinal diseases of children," would, I think, not require consideration, save in a few rare instances, if the feeding of the child were properly accomplished.

In other words, I think the proper attention to the first duty would prevent the intestinal disturbances.

If the latter is an accomplished fact, if the riot in the alimentary canal be well under way, we must ignore the past regime with its opiates and astringents, and administer small doses of the mild chloride ($\frac{1}{20}$ gr.) or infinitesimal doses of the bichloride ($\frac{1}{100}$ gr.) and other germicide and antifermentative remedies, but first and foremost, correct the diet. At the same time if we are in the midst of the heated term we must guard our little patients against exc ssive heat. To this end cooling baths at proper intervals are all important. These have a wonderfully beneficial effect upon the nervous system which is greatly disturbed.

Over-feeding is frequent at all times but specially so in hot weather (when the food supply should in reality be somewhat diminished), owing to the ever present thirst.

Plenty of cool pure water (sterilized by boiling and placing in the sealed "Mason jar" and kept in the ice chest, and not polluted by the placing of ice in it) should be given freely to the babes of all ages; their thirst will then be abated and less food will be taken.

Another important point which should not be overlooked is the danger of "taking cold" even in hot weather. Extreme and pronounced currents of air should be avoided. A great protection to the digestive apparatus of the little one is a flannel bandage over the abdomen, which should be worn till the child is at least five years old, and good rather than harm would result from its use throughout life.

Cholera infantum. This last in the trio of subjects before us follows in regular sequence, and in the majority of instances would "die a borning" if the two subjects which precede it were properly handled. In other words, in my judgment cholera infantum, like cholera or more properly speaking cholera morbus in the adult, would never occur if the feeding problem were properly solved, or in case of error there, if the resulting intestinal war were suppressed before it reached the culminating point.

The Polyclinic.

MEDICO-CHIRURGICAL.

AS a counter-irritant in glandular swelling Pancoast prefers biniodide of mercury to tincture of iodine, as the former does not color the skin, and therefore allows one to see what is going on.

NERVOUS DIARRHŒA.

The case which I am about to describe cannot be brought before the class, because if she were to appear in this room she would at once be seized with a violent desire to evacuate her bowels. As it is, she remains in comparative comfort in the waiting room, because she knows there is a water-closet close at hand. If another patient were to enter and close the door this lady would begin to get uneasy, and if the door were not soon opened she would be compelled to go hurriedly in search of another, or would soil her clothing. This affection has existed from childhood; it has resisted every form of medicinal treatment. Sometimes she will come to my office and will be comfortable until she hears another patient enter the waiting-room. Her face changes immediately. I ask her if she wishes to retire, but she dares not rise, for fear of an accident. I begin to talk carelessly about something else, and in a few minutes she has forgotten her ailment and the rectal spasm has departed. Usually she has several loose evacuations in the morning, and by noon is in condition to trust herself away from her home. She is now twenty-nine, married several years, and has no children. What is the lesion in this case? I have examined her thoroughly, many times, and have found nothing to account for this curious condition. She had some minor affections, none of them causative of diarrhœa, unless as a reflex symptom, but they have all been remedied without helping the principal complaint. She had a relative who was similarly affected, and had anorexia to such a degree that she literally starved herself, and at the post-mortem nothing was found to account for her disease. The present patient was affected with anorexia and nausea last summer until she was reduced to the door of death, and, in fact, was only saved by taking a sea voyage. She has exhausted the materia medica without obtaining any benefit from any drug. Opiates always give rise to violent attacks of cramp in the stomach; astringents constipate, but the disease continues as before. At times the hyperæsthesia of the gastro-intestinal tract becomes so excessive that we fear the gravest results.

I bring this case to your notice particularly that I may impress upon your minds the truth that the giving of drugs is not the sole function of the physician, nor the most important, While no remedy of this kind has had any real effect upon the disease, yet each new one which has been tried has seemed to help her for a few days. The effect has been purely psychic, but each has assisted by giving her a few days of ease, during which she has eaten heartily and retained her food. Besides this I have cudgeled my brains to find new diversions for her, new themes with which to occupy her thoughts and draw them away from her condition. She has gone on various little excursions, performed various little tasks, and been encouraged to make herself actively useful in relieving the sorrows of others. As a result, she is to-day looking better than for years. The flush of health is on her face, she walks miles without fatigue, and while her malady still exists, it is not nearly so persistent or so annoying. Taken altogether, she is vastly improved, and I have every reason to believe that by persisting in the same course she will eventually recover completely.—*Waugh.*

PENNSYLVANIA HOSPITAL.

NEPHRITIS.

LONGSTRETH presented a peculiar case of nephritis. The patient was a stevedore, aged forty-seven. Some years ago he suffered from malaria, and when young he had scarlet fever. He now complained of trouble in his chest only. Had marked dyspnœa, but no orthopnœa. Percussion elicited a dull and diminished pulmonic resonance. Pulse and respiration were 72 and 38 respectively. Temperature subnormal. Suspecting trouble elsewhere, the urine was examined. It was clouded and smoky in appearance, containing granular casts, blood corpuscles, and a large quantity of albumen—1 per cent. dried. Specific gravity, 10.18. Bowels had been quite free. The tongue was heavily coated, and there was a marked œdema of the feet. He was given two drachms of the infusion of digitalis every third hour, with a view to overcoming the stasis of blood, existing in the kidneys, by increasing the heart's action. To clean the tongue, calomel and soda were given. The doctor believed the pneumonic condition was incidental to the renal trouble, and that it would disappear with the restoration of the renal circulation, that it required no treatment. The blood stasis in the kidneys was due to an acute inflammation of these organs, already in a sclerotic condition. The peculiarity of the case was that there was no increase of urine or any marked pain to call patient's attention to his renal trouble. It was a case in which one might have easily erred in diagnosing.

COOPER HOSPITAL.

DISLOCATION OF THE SPINE.

TRAUMATIC dislocation of the vertebræ rarely occur, without the concurrence of a fracture, except in the cervical region, where the articular processes are more oblique than in any region of the spinal column, and where the varieties of movement in the spine are the greatest. Not less rare are dislocations of the ribs from the transverse processes of the vertebræ. In injuries to the dorsal or lumbar regions of the spinal column, a dislocation can generally be excluded, unless associated with a fracture of the vertebræ.

"Spontaneous" dislocations of the vertebræ, as well as angular curvature, may take place in Pott's disease. The pus in dissecting its way downward may strip off the periosteum and the common ligament, disorganize the inter-vertebral substance, and thus favor dislocation.—*Godfrey.*

The Dietetic Gazette:

A Quarterly Journal of Physiological Medicine

New York and Philadelphia, July 13, 1889.

WILLIAM F. WAUGH, A.M., M.D., Editor.

REPRESENTING THE
PHILADELPHIA MEDICAL TIMES.
THE MEDICAL REGISTER.
THE DIETETIC GAZETTE.
THE POLYCLINIC.

PUBLISHED UNDER THE AUSPICES OF THE
AMERICAN MEDICAL PRESS ASSOCIATION.

Address all communications relating to Editorial or Subscription business to THE MEDICAL PRESS COMPANY, LIMITED, 1725 Arch Street, Philadelphia.

Address all communications relating to Advertising to THE MEDICAL PRESS COMPANY, LIMITED, 9 East 17th Street, New York.

ANNOUNCEMENT.

WHILE this number is issued under the title of THE DIETETIC GAZETTE, it is in fact a sample number of THE TIMES AND REGISTER. The points of difference are that the GAZETTE is devoted to dietetics alone: and the departments are arranged somewhat differently. In the weekly editions these consist of:

1. Clinical Lectures.
2. Original Articles.
3. The Polyclinic.
4. Editorials.
5. Annotations.
6. Society Notes.
7. Foreign Letters.
8. Letters to the Editor.
9. The Inquirer.
10. Book Reviews.
11. Gleanings.
12. News and Miscellany.

For the information of the many thousands to whom this Journal comes for the first time, we may say that it is formed by uniting in one the Philadelphia *Medical Times*, *The Medical Register*, *The Dietetic Gazette* and *The Polyclinic*. It is the intention of the managers to add other periodicals from time to time. By so doing we obtain the following advantages:

1. We have a subscription list so large that we can afford to give our readers a larger and better journal than any which has a limited circulation. It costs but little to print a few thousand copies after the first has been run off.

2. By uniting a number of our best writers in the editorial corps, the Journal will give fresher and more varied matter than any one or two men could provide. In union there is variety as well as strength.

In politics, the Journal is independent. It is ruled by no college, clique, society, publishing or manufacturing firm, but is published solely in the interest of the medical profession. We have sought to render its interests general by selecting the members of the Press Association from every part of the country. We seek to make it essentially a practitioner's journal. In order to bring it within the reach of all we have decided to put the price down to $3.00 per annum; not that we consider it in any respect less valuable than the five-dollar weeklies, but because we find we can publish a weekly at the price stated and make a fair profit; and because we would rather have 10,000 readers at $3.00 each than 5000, at $5.00 each. Our columns are open to our readers who desire to record their experiences in practice. In the department headed "The Inquirer," will be printed queries and answers; the latter being furnished by our readers or by members of our staff. In every way we will endeavor to make our journal what we desire it to be: a necessity to every person engaged in the active practice of medicine.

THE AMERICAN MEDICAL ASSOCIATION.

THE Committee on Dietetics received a communication which will be found in another column, requesting the Committee to have analyses made of the various prepared foods to be found in the market.

It was determined to accept the suggestion, with the following recommendations:

1. Profs. Vaughan, of Ann Arbor, and Chittenden, of Yale, are designated as the proper persons to conduct such an examination.

2. They shall purchase the foods in the open market, without the concurrence of the manufacturers.

3. They will be recompensed by the Committee, out of funds to be raised by it, except in cases where the manufacturer is desirous of having his food examined and is willing to pay the cost.

4. The reports shall simply state the composition of the foods examined, without giving any recommendation or condemnation; the report being intended simply to supply information from an independent source as to the true composition of these foods, leaving the physician to use his own judgment as to their employment in his practice.

It will thus be seen that the Committee has taken every precaution to prevent this investigation being turned into an advertisement, and yet to present to the profession an unbiased report upon these valuable products.

In theory, the manufacturers seek to deprive the foods of all inert elements, and to present the nutriment in that condition in which it is most readily appropriated to the use of the consumer. In the proportion in which these objects are attained, the product is valuable. If the claims of the manufacturer are not true, the profession ought to know it. If the food be indigestible, unpalatable, or wanting in any of the essential elements, in a word, if the object aimed at be not attained, the physician ought

to know it; and so should the manufacturer. No amount of artificial "booming" can avail in sustaining a food that is intrinsically bad. Sooner or later the inexorable law of the survival of the fittest will bring about a victory to the one which deserves it. This may be seen in the fact that many of the foods whose ornate devices formerly covered the advertising pages of our journals, have disappeared from public view. Ingeniously worded advertisements and testimonials of analytical chemists who are paid by the year, or who are themselves the inventors of the articles they laud, may succeed for a time, but real worth is sure to tell in the end. As trials result in failure, the receipts from sales fall off and advertising bills cannot be met; so that the evil brings about its own cure. It is easy to see, therefore, how important this investigation is to the persons who are investing their means in the manufacture of these foods. If they are working on a mistaken idea as to the value of their foods, they cannot know it too soon. If their products are intrinsically bad, they had better stop at once; if they are imperfect, we may be enabled to suggest the needed alteration. One food has been unmercifully condemned, when it simply requires the addition of a little cream to each feeding-bottle, to make it an ideal baby food. Another needs powdered dried beef and bone to make it the most highly concentrated and nutritious food in the world; containing every element necessary for sustaining life.

Hitherto, the manufacturers have been practically educating the profession in the matter of digestion, but by the action of this Committee we are at last put in the proper attitude; that of stating our wants and leaving the manufacturer to supply them. The high standing of the analysts appointed will give their report the utmost value to every practising physician.

As it is necessary that there shall be entire independence on the part of this Committee, and as the questions to be settled interest the physician more than any other, it has been determined to ask for contributions from physicians to defray the expenses of this investigation. This journal goes to 86,409 physicians, not one of whom but is interested in this question. If each of them were to forward us so trifling a thing as a two cent stamp, the sum realized would be sufficient for the purpose. But as we are fully aware of the neglect which too many of our brethren show towards their interests, we will assume that one out of every five will respond; and, therefore, we ask that each reader will send us ten cents to further this work. Contributions may be sent to the office of this journal.

* * * * * *

Scarcely less in importance are the recommendations made by the Committee, looking to the formation of commissions to report upon the subjects of feeding in various disorders. In the French Academy of Medicine the custom prevails of appointing one member to make the investigations and frame the report, and several others, generally dignitaries, who advise with him, revise his report, and give it the sanction of their names. This commendable and efficient method has been adopted by Dr. Wood, and the commissions will be appointed in accordance with it.

Dr. Wood, himself, will report upon proposed legislation to prevent the adulteration of food; Dr. Cutter upon the preparation of food for the household, and also upon nourishment in Bright's disease and other wasting diseases. Dr. Waugh will report upon the feeding of fevers, etc.

There are also to be appointed reporters upon the diet of diabetics, consumptives, nervous cases, etc. Should these projects be carried out, they will result in a series of papers of far greater value than those ordinarily presented to societies.

The elements of success are, first, a thoroughly capable reporter, who has time and opportunities for research; second, several other members who are sufficiently interested in the subject to give the reporter efficient assistance; third, the hearty cooperation of all others who can furnish materials of value to the reporter. Other subjects than those mentioned may be added to the list, if it is thought advisable.

With such an amount of work cut out for it, we ask for the Committee of Dietetics the support and coöperation of the whole medical profession in the endeavor to make these reports an honor to American medicine and of value to the world.

Annotations.

COW'S MILK APPROXIMATING HUMAN MILK.

IN Dr. Brush's remarks at the Section on Pædiatrics, etc., he spoke of the possibility of developing, by selection and breeding, a race of cattle whose milk will approximate that of the human female; and thus be especially fitted for the nutrition of human infants.

If it were possible by any such process to transform a cow into a woman, the project would receive our approbation. But if success crowned the enterprise, the result would not be human milk, but a poor, vitiated abnormal secretion, which would be unfit for food. We prefer to use only an average, strictly normal, cow's milk for the nutrition of infants. Even when the milk deviates from the average standard, it is not advisable to use it. The Alderney cows give a secretion rich in fat and poor in casein. Skimmed Alderney milk, therefore, represents human milk more nearly than that of ordinary cattle. But in practice, it is better to use the milk of ordinary

cattle for infants; even setting aside the danger of tuberculosis, to which Alderneys are specially liable. In fact, the analogy between the milk of the lean Alderney, and the abundant, fatty secretion of the consumptive woman, is very close.

STERILIZING MILK.

IT is not necessary to invest in a sterilizing apparatus, as any housekeeper can arrange one equally efficient for herself. All that is necessary is to have some bottles, capable of containing the milk to be used in a day; each large enough to contain what will be needed at one time. These bottles and their corks should be thoroughly cleansed by boiling in a solution of washing-soda. The corks should be selected, and of the best variety.

When the milk is brought to the house, it should be placed in these bottles, which should be arranged on a wire frame in a pot of water, and boiled for fifteen minutes. They should then be corked securely and placed in the refrigerator with the ice *upon* them, not under them. In the country, they may be lowered into the well. Milk thus treated will not only keep sweet and fresh, but almost any impurity it may originally contain will be rendered innocuous.

The flavor of boiled milk is unpleasant to many persons; but this may be remedied by the addition of a little coffee or cocoa. At any rate, one must not expect too much in this world; and for the sake of safety put up with the unpleasant taste, or learn to like it.

THE announcement of M. Brown-Séquard, to which we alluded in our last number, has created a profound sensation. The celebrity of the renowned physiologist gives a weight to his theory which prevents the ridicule which would otherwise assuredly follow. The fact that the experiments reported date from 1869 will suffice to answer the charge that the whole affair is but the chimera of a brain in its dotage; for at that time he was in the full vigor of middle age. He reports that the good effects are produced by injecting subcutaneously the blood from the spermatic veins, mixed with the fluid expressed from the testicles and a little water. Young and vigorous dogs were chosen to supply the fluid. Injections of serum produced no effects excepting abscesses.

On its face, the affair looks like a return to a mediæval superstition. But, surely, if there be a lesson which men of scientific proclivities ought to have learned by heart, it is that "there are more things than their philosophy e'er dreamed of." It is quite safe to say that the Philadelphia profession, which denounced the physicians who were so lost to their principles as to use anæsthetics, who petitioned against the introduction of gas as an illuminant, and who but two years ago pooh-poohed Whittaker, when he demonstrated the tubercle bacillus, will not bestow much thought upon the great Americo-Frenchman's alleged discovery. But in all quarters there will be an immense amount of experimenting done, with patients who imperatively demand that this chance of restoration to virility shall not be lost. And the calls for lamb fries at the restaurants will multiply. And out of it all some good will come; even if it be but the elimination of another error.

RICKETS.

IN London it has been impossible to raise the lions born at the Zoölogical Garden; all dying of rickets. Lionesses do not suckle their young in captivity, and the young monarchs were fed on old and tough horse-flesh. After losing twenty litters, one was fed upon chopped meat, pounded bones, and cod-liver oil; and this litter survived.

There are few, if any, of the artificial foods which would not be better if a little cream were added at the time they are given.

Beef extracts are now universally regarded as simply bases for more or less agreeable stimulating drinks. They have little or no nutritive value, but are in truth rather composed of excrementitious elements; so that beef-tea has been said to differ but little from urine. One beef preparation claims to be made by adding to the extract the dried and powdered muscular fiber from which it has been prepared; making a truly nutritious and palatable preparation. If to this were added a small percentage of finely pulverized bone we would have the most valuable artificial food ever prepared, for weakly infants and invalids, and for rickety children; a highly concentrated nutriment. The addition of fat must, however, be made at the time it is eaten; as no animal fat can be allowed to remain in a food which is intended to be kept an indefinite time before it is eaten, unless it is hermetically sealed. Even then, it is apt to become rancid. Possibly some vegetable fat, like cocoa-butter, could be utilized, but the experiment has not been tried. It seems singular that manufacturers go on imitating an extract which has been proved to be worthless, when the field is open to them for the introduction of so much better products.

Society Notes.

AMERICAN MEDICAL ASSOCIATION.

SECTION ON DISEASES OF CHILDREN.[1]

First Day, Tuesday, June 25.

J. A. LARRABEE, M.D., Chairman.

THE Chairman called the Section to order, and read an

ADDRESS ON PÆDIATRICS,

which he said is not a forced specialty, as the diseases of children require particular study. He deplored the fact that so many practitioners are so unfamiliar with the symptomatology of infantile disorders. He considered that, from a proper deliberation on the subjects connected with diseases of children, wise and wholesome laws would originate to prevent disease. Infantile mortality, from preventable causes, is far greater than it should be. The Chairman expressed

[1] For the report of this Section we are indebted to the *Medical Record*.

the hope that the Section would formulate and adopt some resolutions prohibiting the publication of any statements, either laudatory or condemnatory, of any proprietary preparations of infant foods.

Dr. T. B. Greenley, West Point, Ky., read a paper on

THE MANAGEMENT OF INFANTS DURING THE FIRST YEAR.

The paper dealt almost exclusively with gastro-intestinal disorders. The author spoke of the predisposing causes of mortality—intemperance, syphilis, etc. In feeding children he believed that pure cow's milk is better than the diluted milk. He objected to the use of starchy foods. If a wet nurse be selected, she must be carefully watched, as she may neglect her foster-child, or administer an opiate or alcohol. Dr. Greenley considered that mothers who allow their infants to be nursed by hired women are often guilty, unintentionally, of infanticide.

Dr. E. F. Brush, of Mt. Vernon, N. Y., read a paper entitled

COW'S MILK FOR INFANT FOOD.

Dr. Brush commenced by saying that the medical profession was agreed that nothing equalled good cow's milk as a food for infants, and, therefore, it was to be regretted that attention had not been given by the profession to reforming the breed of cattle and the handling of milk, than to the question of substitutes for it. In milk for infant feeding there should be considered, 1, the variety of fats; 2, the amount of albuminoids; 3, the amount of salts; 4, the handling of the milk; and 5, the health of the cow. 1. As regards the fats, he pointed out that the usual processes of chemical analysis led to an underestimate of the fats in cow's milk, and that of these fats we have no late authoritative analysis, a neglect on the part of chemists which leaves us in doubt as to which of the fatty acids are the mischief makers in milk. These fatty acids have more to do with the development of poisons than have the albuminoids, and are the cause of digestive derangements. 2. The albuminoids vary considerably with the time or habit of extracting the milk, that extracted every two hours not being likely to possess as much or as ripe albumen as that drawn off every twelve hours. In health the albuminoids are constant, but materially affected in disease. This change is not suprising when we examine the mammary sources of milk in disease, for then there are found inflammations, calculi, clots of fibrin, etc., while the gland is at the same time subject to infiltrations, tubercular deposits, and eruptive diseases. In all cases, any variations in the amount of albuminoids must be ascribed to sickness. 3. The salts also have not lately been determined by chemists, and we do not know how constant the occurrence of these salts may be, though we can assert that they are influenced both by the health and the food of the animal. Hence, the land on which a cow is pastured will indicate fairly what we may expect to find as salts.

The nutritive value of the sugar is overestimated, as is shown by the milk of carnivorous animals. Condensed milk, or concentrated sugar of milk, is not to be recommended as an addition to milk, but cane-sugar should be preferred. The chemist's ideal food is a failure, and the idea that milk must contain such and such constituents in such and such proportious is a popular error. 4. The cow must be studied, "for milk is a scavenger of the cow's body," and if it does not nourish the infant she is sick, or the milk badly handled. A faulty condition of the cow is indicated by the albuminoids, bad food by the fats and salts, and bad handling by the ptomaines. The cow has an abnormally high temperature, her organs of generation are in unnatural activity, and she is made a machine for producing milk. It is no wonder then that she is, as a rule, an unhealthy animal. This delicate animal is rarely fed properly, owing to the low price of milk, and the same cause compels the farmer to utilize every drop of milk, be the cow sick or well. Good food is the prime essential for producing good milk. 5. Milk is affected by its surrounding in the cow-house, and the method of getting rid of the odor by saltpetre cannot be too severely censured, for the addition of the niter united with the glycerides may produce poisons approximating to tyrotoxicon. No chemical substance should ever be added. Milk should not be conveyed a long distance, for travel deteriorates milk. Light, like heat, hastens decomposition, therefore glass bottles should not be used.

The milk ought not to be given to the infant warm, for then it coagulates like too old milk. Sterilized milk may be employed if we abandon all hope of improving the quality of milk.

To remedy these evils we should have a better cow, one not closely inbred, well fed with good sound food, and well attended to. The cheapness of milk is the reason why we have not better milk, and the inferior milk suggests the use of substitutes. It the price of the latter were added to the price of such milk, the extra money would enable the farmer to buy better cows and better food, and improve the quality of his products. This he ought to be compelled to do. Let us not recommend patent baby foods, but good, high-priced milk, and then if any trouble arises we can lay the blame on the milkman. Dairies for supply of infants' food should be under strict sanitary supervision. Such an ideal dairy should consist of spayed cows.

Dr. J. A. Jeffries, of Boston, said a large number of women cannot feed their babies, and many will not; hence the necessity for a proper supply of cow's milk. It is important to obtain that with fat as near like the mother's as possible, that the proper adipose tissue may be deposited in the infant's body. Recent analyses show that both the fats and albuminoids vary with the condition of the mother. A child did badly: the mother's milk was found too high in albuminoids, and on dieting the mother the child recovered. Milk sugar is a valuable aliment and not so liable to fermantation as cane sugar. Where milk can be got to the child within three or four hours after drawing, sterilization is not so important, but when, as in cities, twelve or twenty-four hours must elapse, it should be sterilized immediately on being drawn, and then forwarded in sealed bottles.

Dr. Early, of Pennsylvania, considered diseases of cattle a frequent source of contamination of milk and referred to his investigations of dairy farms near Philadelphia and Camden, where milk from animals sick with pleuro-pneumonia was supplied to consumers.

Dr. Sears, of Texas, doubted if disease was conveyed by milk; certainly not to adults.

Dr. Christopher, of Cincinnati, related the results of his inspection of dairy farms near Cincinnati. Cows fed on distillery slops were much handsomer in appearance than those properly fed, and their milk was richer in cream. There is a peculiar condition of the albuminoids in this milk leading to rapid decomposition. He did not agree with Dr. Brush that the fatty acids were the poisonous elements. Ptomaines are nitrogenous bodies and cannot be formed from fats.

Dr. Brush, in closing the discussion, gave prominence to the points that living foods contain some element lacking in preserved foods. Condensed milk may be perfectly pure, but it has gone through a process that robs it of some nutritive quality. So with various artificial foods, chemically desirable. The distillery-stable cows are sleek looking, but they are œdematous, not fatty. It is a fact of observation that the amount of fats and salts in cow's milk can be altered by feeding, but it is only disease that causes a variation in the albuminoids given by any individual animal.

Dr. Peter Hooper, of Philadelphia, read a paper entitled

INTESTINAL DISEASES OF CHILDREN DURING HOT WEATHER.

The author considered the causes of these diseases as mainly heat, impure air, and improper food. He believed the local abstraction of heat from the bodies of children suffering from entero-colitis or gastro-enteritis as productive of good. Cold water and ice internally, and cold compresses to the head he considered beneficial. He also believed in cooling the sick room artificially by the use of large pieces of ice. The author gave the history of a baby aged eight months, where a temperature of 109⅘° F. in the axilla was reduced in half an hour to 105° F. by the application of ice to the spine. The severe nervous symptoms were relieved by this treatment, though no medicine was given. Some entero-colitis followed the acute attack, but the child was always more comfortable when cold was used internally and externally.

In speaking of the use of milk foods, the author related as his experience that the children who use them do not grow so strong, so muscular, or so rapidly as they should. In cases of failure of mothers to nurse their children he advised the use of sterilized milk.

The author mentioned as the possible treatment of the future in cholera infantum the opening of the abdomen and washing out of the intestinal tract. The use of inunctions of olive oil were spoken of as beneficial.

Dr. J. Solis-Cohen, of Philadelphia, thought the use of ice preferable to antipyretics.

The Chairman thought that thermal diarrhœa is best treated by cold. He did not believe that cholera infantum ever began as a simple diarrhœa, as mentioned by the author. He spoke of the advantage of the use of small doses of morphine and atropine hypodermically, the effects being quick, and a dilatation of the peripheral capillaries thus relieving the intestines. He advocated the use of salines in entero-colitis in preference to castor oil.

Dr. E. F. Brush, of Mount Vernon, N. Y., thought that the cases of acute gastro-enteritis in children were produced by the cows eating poisonous weeds.

Dr. W. P. Watson advocated the use of hot water as a drink for children with intestinal disturbances.

COMMITTEE ON DIETETICS.

The meetings of the Committee on Dietetics of the American Medical Association were held in the Casino Building, Newport, June 26 and 27, Dr. E. A. Wood, of Pittsburgh, in the chair.

Dr. Woodbury read a communication and presented samples of a glycerite of calf-pepsin. (See page 249.)

Dr. Wood, of Pittsburgh, in opening the discussion referred to a plan he had adopted of preparing cow's milk for infants. The milk should be from a clean dairy and from healthy cows; it should be placed in glass jars of the size required for use, which can be tightly closed with a lid after being entirely filled with the milk. When kept from contact with air in this way, the milk will not turn sour for several days. When the jar of milk is opened, one half is to be treated with rennet and the curd separated, the whey is then added to the other half of the milk and a little cane sugar added. This prepared milk is then kept in a closed glass vessel, and portions taken from it for feeding the infant as required; the milk food can be warmed, but not made hot. He claimed that fresh milk is aseptic, and that it can be kept so by excluding air; he considered dilution of the milk necessary, but prefers to use whey, for this purpose, to water which may be contaminated. Cane sugar he likes better than milk sugar. For coagulating the milk he thought the preparation just presented an available one, and more reliable than rennet.

Dr. Waugh, of Philadelphia, said that he considered the principle advanced by Dr. Woodbury of great importance. There can be no doubt that nature has provided in the digestive apparatus of each animal the most appropriate means of digesting the food peculiar to that animal. These adaptations of nature are sometimes made with the utmost nicety; and as yet our knowledge of physiology is not sufficiently exhaustive for us to judge of what amount of harm may be done by disregarding these conditions. Until we have such an insight into the digestive processes, it is best to digest milk with its natural digestant: the pepsin of the calf.

Dr. Christopher, of Cincinnati, spoke of the importance of improving the breed of cows, so that a supply of milk better suited for infant-feeding could be had. Referring to the difficulty of digesting cow's

milk he said that in a child fed on milk at five o'clock, the stomach was washed out at nine, and casein was still present, partly broken up and partly rendered translucent.

Dr. J. A. Cutter, of Boston, said that he had devoted attention to microscopic examination of the fæces and stated that, by this means, much could be learned about digestion. In chronic cases he had found advantage by varying the form in which pepsin or pancreatin is administered.

Dr. Chenery, of Boston, thought commercial pepsins very unreliable, and that they were capable where there was ulceration of the bowel of causing a form of blood poisoning. He referred to a case of dysentery, which died with symptoms of septicæmia after administering Fairchild's pepsin.

Dr. Waugh. It is not necessary that there should be an abrasion in order to have absorption of poisons from the intestinal tract.

The pepsin in Dr. Chenery's case may have been in a state of decomposition; hence we are unable to determine whether it was a case of pepsin poisoning or of septicæmia. But there is another question which arises in regard to the use of the powerful pepsins now being introduced. It is well known that vitality does not protect the tissues from the action of the digestive fluids, as has been shown by the experiments upon the ears of living rabbits, which are digested by the gastric juice. Is there not, then, danger that when these very powerful pepsins are introduced into the stomachs of infants, especially when the resisting power is lessened by sickness, there may be a digestion of the tissues? For this reason, and because it is well to keep in mind the fact that pepsin is not truly a medicinal agent, but that its action is directed to the food instead of to the body, I approve of Dr. Wood's method of using it.

Dr. Wood. Under the action of commercial pepsins that are contaminated with bacteria, ptomaines may be formed in the intestines and cause death. There are many cases of supposed rheumatism that are no more rheumatism than they are cholera Asiatica or yellow fever, but which are cases of poisoning by ptomaines.

Dr. E. Cutter, of New York, asked if Dr. Woodbury had any evidence that bone digests in the human bowels?

He asked this, for the only evidence that bone digests in man he had found was noted in the recent reports where resection of the intestine had been done and tubes of bone were employed, that the tubes would dissolve after a short time, thus showing a digestion of the same; but these were "decalcified."

Dr. Woodbury, in reply to Dr. Cutter, said that there is a great diversity in the digestive capacity of men, and he had no doubt that many individuals could digest bone, but ordinarily it would act as a foreign body and cause irritation.

Dr. Cutter, continuing, said that air is food; mineral food at that, as water is mineral food; his definition of food being any substance from without taken into the human body, which becomes a normal constituent part of that body. Then as the oxygen and nitrogen of the air become component parts of the body they are food. This idea was an old one. Once, in going to New York from Boston, he sat near a man in the cabin who had open on his knees a book in Hindostanee, and in his hands he had an open book in French. He was a missionary from India, and spoke twelve languages. On being asked if he thought that English would be the universal language, he said "No, it is not expressive enough." For example, we say in English "a man walks out, and a dog walks out," but the Hindostanee language puts it, "The dog walks out and the man goes forth 'eating air.'" This expression is three thousand years old.

Again, the same idea is met with in Plutarch's Lives. A late account of the gypsies states that they every morning go out early and inhale full breaths; hold them; pound their chests hard in expiration, and then inhale deeply again, and so on. This they call "eating air." Newport is built up on this idea of "eating air." He said further, that he never could believe that nitrogen was an inert substance in the air. Just as the false vocal cords were denounced almost useless things and hence called "false," and as it had been found out that they were as active as the true vocal cords in the control of the expiration, —and he had, following the nomenclature of "vocal bands," called them "breath bands;" — so he thought that some time the active function of nitrogen in the air would be found out. It might be by guesswork, as those famous archeological inscriptions were made out, still it would come in time, whether as a result of thunder-storms or in some other way. The amount of nitrogen consumed by the human race daily was enormous and could not be overlooked.

Dr Cutter also expressed his great interest in the work of the Dietetic Committee. He did not want it cut off, but pushed to fruition, no matter who or what opposed. The future of medicine lies in the food question. He was in favor of the Association recommending that State legislation should be taken as to proprietary foods like that now taken in relation to fertilizers (soluble mineral plant foods) by the Experimental Statutes in Agriculture. States were doing better for *hogs* than for man, he thought; but man was the most important article of value in any commonwealth, and should be protected.

Dr. Christopher. Ptomaines will not only produce the effects described in Dr. Chenery's case, but also will actually produce lesions; structural changes may be produced by chemical agents. Gout and rheumatism have been ascribed not to an excess of urea in the blood, but its formation near the joints under the action of a special agent, An illustration of this is seen in guanine gout.

[Dr. Christopher then gave a very interesting account of the relations of nitrogen to digestion. A vote of thanks was tendered him, with the request to bring up the subject at the next meeting in a paper embodying his views on the position of nitrogen as a food and its relation to disease.]

The chairman announced the receipt of a communication relative to the analysis of infant-foods, and on motion it was referred to a special committee consisting of Drs. Waugh, Christopher and E. Cutter. Adjourned.

NEW YORK, June 17, 1889.

To the Committee on Dietetics of the American Medical Association,

GENTLEMEN: It is generally accepted, we believe, as an axiom in dietetics, and scientific research and practical experience agree in demonstrating its truth, that a satisfactory food for infants up to seven months of age must correspond with human milk as closely as possible in the character and proportion of proximate principles. We have expended much time and a large amount of money in our endeavors to produce an infant food which would stand this crucial test. In this work we have enjoyed the assistance of some of the leading physicians both of this country and Europe, who have been distinguished by the attention they have given to the subject of infant feeding, and have been directed by some of the most eminent physiological chemists in the world. Fully recognizing the fact that for very young infants, cereal, or starch food, is unnatural and is contra-indicated, we have for some time been directing our experiments towards the production of a food prepared entirely from milk, in which all its constituents should be represented in a similar proportion to that of human milk, which the finished product would closely imitate. As a result, we have succeeded in obtaining a food which is the nearest approach to human milk that can be produced. This food is prepared wholly from cow's milk, with the exception that the fat of the milk is partially replaced by cocoa-butter. This was done at the suggestion of Prof. Attfield, of London, because of the fact that the fat of the milk very rapidly becomes rancid and will not keep in any considerable quantity, while the oil of theobroma remains permanently sweet, and is as easily digested as milk-fat. The fact that a food containing a large proportion of milk-fat will not keep for any length of time is well-known, consequently it becomes necessary to substitute a fat which is permanent and unchangeable. Moreover, a pure vegetable fat has especial advantages for this purpose over animal fats derived from sources liable to be contaminated. Cocoa-butter closely resembles milk-fat in composition, differing principally in the absence of the constituent which produces rancidity. The following are the processes which we adopt in making this food: Having added the cocoa-butter, we partially digest the milk with fresh extract of pancreas, at a temperature of 105° F., a sufficient length of time to render about one-fourth of the casein soluble; the remainder of the casein is by this process rendered, in its physical character, like the casein of human milk, and the fat partially prepared for assimilation. We now add sufficient pure milk sugar to make the proportion of carbo-hydrates equal that of a sample of average, good human milk. The mixture is finally heated to a temperature sufficient to thoroughly sterilize it, then it is evaporated in vacuo and ground to a fine powder. It is finally placed in hermetically sealed packages, by which it is kept in a perfectly aseptic condition. Being free from bacterial contamination, and practically free from moisture, this food will keep unchanged for any desired period of time. In order to prepare the food for use, it is only necessary to add to the powder sufficient water to replace that taken away by evaporation. Analyses show that, by the simple addition of water, this milk-powder becomes practically identical with human milk in composition; and both laboratory and clinical experience have proved that it equals human milk in digestibility, and is an acceptable substitute for it. A sample of this preparation will be found to contain, closely:

℞.—Fat	10 per cent.
Milk sugar	64 "
Albuminoids	19 "
Moisture	3 "
Mineral matter	3 "
Lime phosphate	½ "
Sodium chloride	½—100 per cent.

The last two constituents are in addition to the natural mineral matters found in the milk, and have been introduced by advice of the eminent authorities already referred to.

Having thus produced, upon scientific principles, a food which represents human milk as closely as possible, and one of which the intrinsic merit will commend it to the medical profession, we find ourselves confronted by innumerable statements from parties engaged in making infant food, with most extravagant claims to the profession of the superiority of their products, each claiming to be the best. The hesitating practitioner is confused by so many conflicting statements, and, being unwilling to subject his patients to experimentation, in his perplexity he is tempted to throw away the wheat with the chaff, and hastily conclude that there is little value in any of them. Others, who more carefully investigate the matter, may finally decide that one food really possesses merit, but are prevented, by a mistaken sense of ethics, from publicly recommending this food to their colleagues.

Not fearing the results of honest investigation, we ask that this whole matter be made the subject of a crucial test, conducted in a manner which shall be beyond all criticism. We, therefore, present the case before you as a committee of the highest authority, and ask for an investigation of all the infant foods now upon the market, the tests to be thorough and the analyses made by competent and unquestioned authority of your own selection, which we hope will settle the question definitely. As the hot season is now upon us, the prompt settlement of this subject is all important. We would suggest that the Professor of Physiological Chemistry at Harvard, Yale, or Johns Hopkins, or other equally competent authority, be requested to purchase samples of all infant foods now in the market, and make immediate examination of them upon the following points: the percentage of fat, of milk-sugar, of dextrine, starch, and other carbo-hydrates, individually, or albuminoids, soluble, and the character of the insoluble, and the amount of mineral matter and its character. The report to state the exact proportion of the foregoing constituents in each sample, and of any other constituent found therein. These analyses must be based upon the foods as actually found in the market, without further addition or preparation.

In order to facilitate this examination, if agreeable to your honorable Committee, we offer to pay the entire expense of such analyses as soon as they are published, by your direction, in the Journal of the American Medical Association. We also offer to pay the expenses of the chemists engaged in this work, if they wish to visit our laboratory at Goshen, N. Y., where we agree to afford them every facility for investigating the process of manufacture. We make this proposition in good faith, believing that such an investigation is the only proper method of settling this much vexed question, a question which we regard as of the highest interest to the medical profession and to the community.

In order to identify the prepared milk-powder which we desire to bring to your notice directly, we have styled it "lacto-preparata," which expresses its composition and character as a food.

Very respectfully yours,

REED & CARNRICK.

An evening session was held at which the report of the special committee was presented. It recommended (1) that an analysis of the principal infant foods shall be made under the direction of this committee, and recommended that Profs. Vaughan and Chittenden be requested to inform the committee of the cost of such analyses; (2) that the expense be met by voluntary contributions; (3) that the samples of foods shall be purchased by the committee in open market; (4) that manufacturers be invited to contribute proportionate amounts, sufficient to cover the expense of examining their products, and such foods analyzed as manufacturers are willing to pay for; (5) that ultimately the control of the supply of infants' foods shall be regulated by legislation in the same way that guano and other fertilizers are at present

The report was adopted and referred to the sub-Committee on Infant Feeding, consisting of Drs. Woodbury, Christopher and Rohé.

DR. WAUGH offers the columns of the DIETETIC GAZETTE for the publication of any communications read before the Committee and in every way possible to assist in its work, and, on motion, a vote of thanks was tendered him.

On motion of Dr. Waugh the following were appointed to report at the next session: "On Legislation to Prevent Adulteration of Food," Dr. E. A. Wood; "On Preparation of Food for the Household," Dr. E. Cutler; "On Feeding Patients Suffering with Fever," Dr. Waugh; "On Nourishment for Cases of Bright's Disease and other Wasting Diseases," Dr. E. Cutter; "On Ptomaines in Relation to Disease," Dr. V. C. Vaughan; "On Nitrogen as a Food and its Relations to Conditions of Disease," Dr. Christopher.

The following resolutions were presented by the Chairman:

Whereas, Certain garbled extracts from the proceedings of the Committee and the Section on Diseases of Children have been published in medical journals as advertisements, and, thereby, have reflected upon this Association, therefore, be it

Resolved, That the Committee on Dietetics and the Section on Diseases of Children have not in the past, nor do they now; commend any of the proprietary preparations used as foods, and we earnestly protest against the act of manufacturers in charging partiality for any food, and we hereby condemn the action of those medical journals which have published such advertisements.

Resolved, That a copy of these resolutions shall be sent to the *Journal of the American Medical Association* for publication.

On motion, these were adopted, and directed to be transmitted to the Section on Diseases of Children for conjoint action.

SECOND DAY.

A paper was read by Dr. E. Cutter on Vinegar and Vinegar Yeasts.[1]

The Committee on Dietetics then adjourned to meet at the call of the Chairman.

FRANK WOODBURY,
Secretary.

NEWPORT, June 27, 1889.

Book Reviews.

A TEXT-BOOK OF HUMAN PHYSIOLOGY, including Histology and Microscopical Anatomy; with special reference to the requirements of Practical Medicine. By DR. L. LANDOIS, Professor of Physiology, etc, University of Greifswald. Third American, translated from the Sixth German edition. With additions by Wm. Stirling, M.D., Sc.D., Professor of Physiology and Histology in the Owens College, Professor in the Victoria University, and Examiner in Physiology, University of Oxford. With six hundred and ninety-two illustrations. Philadelphia: P. Blakiston, Son & Co., 1889.

There is no more perfect book of the kind to-day in our language. Its scope and recent careful revision may be said to bring the science of which it treats almost up to the standard of the hour. Fresh from the hands of two such distinguished and eminent authors, it presents masses of facts that are collected from astonishing amounts of work, and which are systematically arranged with the greatest skill, the result both of unusual care and intimate knowledge of the art of teaching.

The different headings are set forth in bold type, so as to be read by one who runs, and the fundamental parts of the work are more heavily printed than the detail of the same.

Adding to the value of the volume are thorough, but not too lengthy descriptions of the apparatus used in pursuing practical laboratory experiments, but these portions are distinguishable from the general text by being printed from a smaller font. By this system of typography one is enabled to select readily such matter as he may be most pressed to obtain and regulate the balance for future consideration, when time is not so important and opportunities are more plentiful.

If the size and price of the book are not considerations, and they should not be in judging of its literary merits, it stands preëminent among the text-books on physiology. With it the lectures of the college curriculum may be most advantageously supplemented, and if opportunity for reading and the eyes of the applicant for knowledge are equal to the task, it might be read and reread many times with advantage. To the practitioner who desires to find the latest and most practical accounts of the labors of the

[1] Will appear in a succeeding issue of this journal.

different authorities it will be invaluable, and no one who follows the higher walks of the healing art, or forms opinions as to the merits of the different methods of practice, should be without a copy of this compilation of the standard authors and investigators. The text refers by name to the discoverers, but unfortunately does not record the pages of the publications in which the whole of the original essays referred to may be found, which seem to be inconvenient omissions.

The illustrations, of which there are one hundred and nine more than in the former edition and two hundred and two more than in the first, both in number and adaptation leave but little now to be desired except their production in different colors, and this in the present state of the chromo-lithographic art would probably so increase the price of the volume as to place it beyond the reach of the majority of purchasers.

The weight and size of the book seemingly are as little as are consistent with its vast scope, and the price compared with that is truly economical. Of the contemporary works, it is the most complete and perfect; in every respect it is to be commended, if we except the mere theoretical danger of its appalling the beginner by its exceeding richness and mass of facts recounted.

The effects of diet, drugs, and many of the changes in physiological phenomena resulting from diseases, are so noted as to show the philosophy of treatment and to bridge over the important neutral ground between this science and the practice of medicine. Yet this very advantage to the experienced practitioner may in some respects serve to embarrass the tyro, who wants rules and fixed methods rather than to be thrown upon his own responsibility.

A comprehensive but terse introduction is given, reciting the salient points as to matter-forces and their conservation, animal and plant life and vitality in general.

Nearly the first fifth of the book may be said to appertain to the study of the blood and the organs concerned in its formation and circulation, and is almost exhaustive of the known and accepted facts of the day. The great merit of these chapters is that they are so arranged as to present the known facts and the theories almost perfectly systematized.

It will not consume much time for an ordinarily fair student to learn the key by which he can quickly select any desired part from the whole.

Respiration, including the structure and mechanism of the organs concerned, the sounds they produce while in action, the quantity of air required for maintenance of health, and the changes in the atmosphere, and the gases, the questions of ventilation, amount of cubic feet of space, area of floors in rooms and hospitals, are given according to the best known scientific data. Finally, while in some books the outline is traced by a historical sketch first, this one gives, at the end of each division, a short but very interesting résumé of the steps of progress and the comparative physiology of the subject as illustrated by the animal kingdom.

Digestion and absorption might with peculiar advantage have had added a treatise upon different foods and their preparation and effects.

With a loss of exactitude that may be pure and undefiled, there is at times a certain German air about the matter, due to long and ponderous compound words, that is oppressive for any but scholarly readers. Thus for the terms cold and warm-blooded animals, we find "Bergmann introduced the word homoio-thermal for the warm-blooded animals (mammals and birds), because these animals can maintain a very uniform temperature, even though the surrounding temperature be subject to considerable variations. The so-called cold-blooded animals are called poikilo-thermal, because the temperature of their bodies rises or falls, within wide limits, with the heat of the surrounding medium." But it will be evident to the reader that the article treating of the heat of animals would be justly liable to adverse comment if the authors who have worked in this branch were passed without notice. Therefore, it can hardly be said to be a criticism that is unobjectionable, although borne out by the facts of the case.

The structure and functions of the kidneys, the constituents of the urine, its changes, spontaneous and fermentative, including the normal and abnormal, are given. The causes of albuminuria are very ably epitomized, set forth with well executed illustrations, both of the histological and the microscopical appearances. The forms of the most approved apparatus for examination and analysis are shown by cuts that are of great value to all who take a lively interest in both the physiology and the pathology of these emunctory organs.

The chapter on the skin as the complemental organ of the above, succeeds immediately after; showing by its classification that the arrangement is excellently chosen to assist the practical man as well as the scientist.

The physiology of the motor apparatus, beginning with that of the simplest ciliary cells, passes to those that at present are only known as pigment cells, soon takes up the structure and arrangement of muscles, giving very thoroughly the minutest histological appearances of the associated tissues, as the fibrillæ, sarcolemma, tendons, bloodvessels, lymphatics and terminal nerve filaments. There is likewise the comparative physiology and histology that throws light upon the study, as demonstrated by Engelmann and others in the muscles of the arthropoda. Schäfer's account of the appearance of the longitudinal transparent and opaque stripes, the primitive fibrillæ and their reversal during the contraction of the living muscular fibres, are also given, with illustrations from Rollett. The "antler-like" terminations of the axis cylinders of motor nerves and their end plates among the muscular fibers are described and illustrated very satisfactorily.

While treating of the source of the energy of the muscles, the fact that proteids may be consumed to eliminate force, is mentioned, but not dwelt upon sufficiently to disturb the accepted views that the carbohydrates are "the chief sources" of the energy.

The fatigue, rigor mortis, the muscle sound, gymnastics, the Ling's, or Swedish system and massage, are explained from a standpoint that comes of the blending of an intimate acquaintance with the subject

and the requirements both the busy student and active physician. Illustrations are given from the instantaneous photographs of Marcy, showing the changes of position in the human being, in slow walking, running and leaping; after which is a dissertation on the voice, particularly the range of it, the articulation or speech; and the voice of animals is considered in its relation to the human.

About three hundred and seventeen pages are devoted to the "general physiology of the nerves and electro-physiology," "physiology of the peripheral nerves," ditto "of the nerve centers," ditto "of the sense organs." Such important observations as are given under these heads must be read. A hasty description would fail to show the skill with which the writers have gradually proceeded in this article from the very simplest to the most complex phenomena. Step by step the structure has been reared with an art that is as delightful as it is wonderful. The subject is the crowning one of the science, and the authors seem to have risen to their most happy and exalted work with an almost imperceptible effort, which is glorious in its results. The comprehensiveness of this portion of the book seems to leave little or nothing to be done until further facts are brought to light. The simple and the complicated "structure and arrangement of the nerve elements," "the chemical and mechanical properties of nerve substance," "metabolism of nerves," "excitability of nerves," "diminution of excitability—degeneration and regeneration of nerves," "the galvanic current," "action of the galvanic current—galvanometer," "electrolysis," and so on to the end through the subject, are treated of in a manner that is far above ordinary work of the kind.

The experimental laboratory fittings, much of which have been devised by the indefatigable investigators during late years, are illustrated unostentatiously, briefly but faithfully described. The electro-therapeutical apparatus, the motor points of the head and the limbs, in a word nearly all that can be relied upon as solidly known facts in this connection, can be found in this volume.

The "physiology of reproduction and development" is the final labor, and might perhaps have been more extended, but for the fact that the book had reached nearly nine hundred pages before this matter is taken up.

The finale is an appendix giving the general bibliography, which in a measure makes amends for the neglect of definite references to volume, page and line of the host of authors referred to in the text. A résumé of the bibliography shows that there are:

Systematic work and textbooks	63
Yearly reports; bibliographical works	20
Historical	12
Encyclopædias	5
Practical works on the laboratory	21
Special laboratory reports	22
Journals; periodicals	75
Histology	49
Physiological chemistry	30
	297

About three hundred works of reference, some of them spreading over many volumes and as many years in their publication. It would overtax the ordinary practitioner or student to even get a hasty glance at the authorities in each case. In such instances that the reader proposed to exhaust the book and its references, it would be well that he should take up a residence in a medical library and devote his life exclusively to the work, unless assisted by a trained corps of clerks.

After reading this work the regret is that there are not more of the same nature. It would be an avis rara indeed where more extended yet concise matter of a solid unaffected style could be found in an equal number of pages of the same size.

The public appreciation is shown in the fact that in the land of its birth six editions have passed through the criticisms of its contemporary authors, and that England and America have profited by it for two editions and commenced a third. T. C. S.

THE HYGIENE OF THE NURSERY, including the General Regimen and Feeding of Infants and Children and the Domestic Management of the Ordinary Emergencies of Early Life. By LOUIS STARR, M.D., Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania; Physician to the Children's Hospital, Philadelphia. Second edition. Enlarged and improved. With twenty-five illustrations. 12mo., 280 pages. Cloth, $1.00. Philadelphia: P. Blakiston, Son & Co.

Dr. Starr has wisely had this edition of his book published in a more popular form than the preceding. There is but little alteration in the book itself, which has the same commendable features and defects which were present in the first edition. The worst chapter is that upon infant feeding; in which Dr. Starr does not seem to be aware of the more recent investigations. The exploded idea of soluble dextrine acting mechanically in preventing the formation of a firm coagulum, still finds place. We must also object emphatically to the use of "nutmeg, sugar, or a little brandy" (vide p. 216) to render a food palatable. If a food requires the addition of such agents to render it palatable, it should be changed for something less disagreeable. The most commendable new feature is the description of a very handy and efficient sterilizer, figured on page 193. The importance of sterilizing all milk used by a family for food cannot be too strongly impressed upon the public.

VASCULAR NÆVI. — Holgate (*Archives of Pædiatrics*) favors the treatment of vascular nævi by injecting them with alcohol.

DIET OF ENGLISH SOLDIERS.—A committee appointed to investigate the subject of soldiers' rations has lately made its report to Parliament. They found that the meat was satisfactory, but that the bread was indifferent; and recommend that those whose duty it is to pass on the quality of the rations, medical and regimental officers, should have a course of instruction that would make them competent to form a proper judgment.

As an inducement to the cooks there is some thought of having a system of rewards for the best dressed dinners in each month.

Medical News and Miscellany.

Dr. R. C. M. Page, of New York, is in Europe.

Dr. Beverly Robinson, of New York, is at Newport this summer.

Dr. Mary Putnam-Jacobi, of New York, is in Europe this summer.

Dr. Oren D. Pomeroy, of New York, expects to visit Europe this summer.

The skin of the frog is now coming into use for the purpose of skin grafting.

Dr. Edward L. Keyes, of New York, is, as usual, at Newport for the summer.

Dr. Henry C. Coe, of New York, has been at the West End Hotel, Long Branch.

Dr. M. Fuller, of New York, has been at the Fuller House, Richfield Springs.

Dr. I. E. Taylor, of New York, was announced as booked for the Elberon, Long Branch.

Dr. H. N. Buckley, of Delhi, N. Y., has been at Prospect House, Conanicut Island, R. I.

Dr. J. M. Turner, of New Brooklyn, makes the Thousand Islands his summer resting place.

Dr. F. Le Roy Satterlee, of New York, occupies his cottage on Clay Street, Newport, this season.

Dr. B. L. Ten Eyck, of Newark, N. J., lately appointed to the Army, has been ordered to Kansas.

Dr. F. C. Fuller, of New York, has his office at the Seabright Inn, Seabright, N. J., this summer.

Dr. Emil Gruening, of New York, has a place in New Jersey, where he usually spends his summers.

Dr. T. M. L. Chrystie, of New York, has been elected physician of the New York State Society of the Cincinnati.

Dr. Thomas H. Bailey, of New York, is at the Ocean House, Long Branch, where he has had headquarters for ten years or more.

The Managers of the Hospital for Children and Females, and School for Nurses, San Francisco, announces that internes may enter there on January 1 and July 1, each year.

The Attending Staff of the Chicago Hospital announces that it will appoint three internes annually, to serve one year, regular vacancies occurring January 1, May 1, and September 1.

A large amount of material intended for this number has been crowded out, and will appear in that of next week. Those desirous of obtaining it can do so by remitting the price.

The National League of Physical Education in France is making great progress in attracting public attention to the value of athletic sports for school boys. The health of the pupils has improved, and the results bid fair to bring about a general enthusiasm upon the subject.

The English Parliament has passed the bill regulating the sale of horse-flesh as food for man; and also that suppressing indecent pamphlets of a pseudo-medical character.

Dr. Thomas M. Markoe, of New York, favors Southampton, L. I., as a summer residence; so do Drs. T. Gaillard Thomas, H. Holbrook Curtis, and P. Llewellyn Chambers.

There are half a million of lepers in India. It cannot be doubted that leprosy is on the increase in many parts of the world. We may live to see an alarming spread of this disease.

The New York Board of Health, last week, reported 1255 deaths from violence, exclusive of murder and suicide, in that city during 1888. Five were by shock from electric light wires.

The promoters of the Medical Women's Fund, Bombay, complain that the Indians display little interest in the project, while they receive with enthusiasm the scheme to provide hospitals for animals.

There is, or was recently, a vacancy in the position of Resident Physician in the New England Hospital, Boston; so Dr. Emily F. Pope, Secretary of the Board of Physicians of that institution, announces.

The *Sanitary Era* claims that the plumber ranks with the physician in looking after the health of the community. Well! well! Who'd have imagined it! However, we hasten to admit that the plumber is the doctor's best friend.

In order to be eligible to an appointment as health officer in England, it will now be necessary to obtain a diploma in Public Health, showing that the applicant has passed a special examination in branches pertaining to that subject.

Dr. McFadyean, the Medical Officer of Health for Stirling, describes a recent epidemic of typhoid fever caused by milk. The milk absorbed the infective germs from the water of a foul drain which communicated with the milk-house.

Miss Cora Thompson, Sub-Dean of the Faculty of the Women's Medical College of the New York Infirmary, is away from town for a time, and her official place is filled by Miss Barrow, who may be seen at the College every morning from 11 to 1 o'clock.

The medical profession of this country has been attracting attention lately in a peculiar manner. Dr. Cronin is murdered in Chicago; Dr. James Downie, a talented but dissipated physician from Glasgow, Scotland, establishes himself in Brooklyn, under the wing of well-known people, and is arrested for the murder of a woman with whom he had run away from his former home; Dr. McDow, of Charleston, S. C., kills an editor, and barely escapes hanging, and Dr. Charles F. Stillman, a talented young physician of New York, finds himself brought into unpleasant notoriety, and forced from some of the high positions he has occupied, for undertaking, though he has a wife, the care and maintenance of Miss Mabel Schaus, the daughter of a wealthy New York picture dealer.

Among the New York doctors who will be busy at city institutions this summer in spite of the hot weather are Dr. Paul F. Mundé, who operates Wednesdays at Mt. Sinai Hospital; Dr. H. C. Coe, who operates Wednesdays at the New York Cancer Hospital; Dr. W. Gill Wylie, who operates Thursdays at Bellevue; and Dr. Van Arsdale, who operates Fridays at the Eastern Dispensary.

In some of the large London business houses the feeding of employés is farmed out at so much per head to housekeepers, whose profits increase as the food they supply is scantier and cheaper. Instead of rebelling against such an imposition and securing justice for themselves, the employés meekly put up with it until some philanthropist finds it out, and asks Parliament to legislate the abuse away.

In true sunstroke we have succeeded best at the Medico-Chirurgical Hospital by giving antipyrin internally or by hypodermic, in doses up to thirty grains, and applying ice energetically, externally, and in the rectum, until the temperature descended to the level of safety.

The great majority of cases, however, are really of exhaustion, due to heat and free drinking, with consequent perspiration and loss of salts. Small doses of brandy, ammonia, wine of coca, selecting a really efficient variety, and hot coffee are efficacious at first; followed by a hot bath, hot beef tea, quinine, or Huxham's tincture.

The use of ice water gives rise to unquenchable thirst. Free imbibition of fluids causes loss of appetite. An excellent beverage for summer is thin oat-meal gruel, with salt, but no sugar, taken as hot as can be swallowed.—*Waugh.*

The New York Polyclinic and Hospital is rapidly and vigorously extending its usefulness. It has recently added to its already large facilities by the purchase of the adjoining four-story building. The new building, No. 218 East Thirty-fourth Street, accurately speaking, has four stories and a basement, and all of this will be devoted to hospital purposes. The main building, Nos. 214 and 216, will remain as before, devoted to rooms for clinical instruction, the top floor only being included in the hospital department. The New York Polyclinic and Hospital claims the honor of being the first in the field in New York as a post-graduate instructor in medicine, and its progress is rapid and steady. It owns all its buildings, and has some of New York's wealthiest and best known men as its supporters. Its past season has been very prosperous, and it has made elaborate preparations for the coming year. The following gentlemen have been recently added to its Faculty: Dr. Thomas R. Pooley, Professor of Ophthalmology, Surgeon-in-Chief of the New Amsterdam Eye and Ear Hospital, Ophthalmic Surgeon to the Sheltering Arms, and Consulting Ophthalmogist to St. Bartholomew's Hospital; Dr. B. Sachs, Professor of Neurology, Consulting Neurologist to the Montefiore Home for Chronic Invalids; Dr. L. Emmett Holt, Professor of Diseases of Children, Visiting Physician to the New York Infant Asylum, and consulting Physician to the Hospital for Ruptured and Crippled; Dr. August Seibert, Professor of Diseases of Children, Physician to the Children's Department of the German Dispensary; Dr. H. Marion Sims, Professor of Gynecology, Gynecologist to St. Elizabeth's Hospital and the New York Infants' Asylum; Dr. William H. Fluhrer, Professor of Genito-urinary Surgery, Surgeon to Mount Sinai and Bellevue Hospitals.

Dr. James B. Hunter, President of the Faculty and Professor of Gynecology, who died on June 11, will be sadly missed, His place in the Chair of Gynecology is to be filled by Dr. H. C. Coe, R.C.S., Surgeon to the New York Cancer Hospital, Assistant Surgeon to the Woman's Hospital, Obstetric Surgeon to the Maternity Hospital, Obstetrician to the New York Infant Asylum, and Gynecologist to the Presbyterian Hospital.

The summer session at the Polyclinic opened on July 1, with a large class. Mr. Willis O. Davis now acts as assistant to Dr. John A. Wyeth, Secretary of the Faculty, in discharging the duties of that position.

The well water at the Lazaretto station is said to be bad.

Dr. Samuel Alexander next season will take the place of Dr. Keyes as Professor of Genito-Urinary Surgery, Syphilology and Dermatology at Bellevue Hospital Medical College. Dr. C. F. MacDonald is another newcomer at the same institution, where he takes the Professorship of Mental Diseases. He has had ample experience in his specialty at the State Asylum for Insane Criminals at Auburn, to which place he was appointed by Governor Hill for six years.

Dr. R. O. Doremus, Professor of Chemistry, will spend the summer at Whitestone, L. I. Dr. Doremus is firm in his friendships, and has seldom taken anything more to heart than the claim that Dr. Fordyce Barker never received a French diploma. Dr. Doremus says the degree was so small that some one suggested it should go upon Dr. Barker's door in place of the customary narrow sign. However small this degree was, it was never so small as zero, as some of Dr. Barker's opponents have thought.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 2, 1889, to July 8, 1889.

Gibson, R. J., Captain and Assistant-Surgeon. Reports arrival July 2, 1889, at Camp Lewis, Fisher's Island, N. Y., in compliance with Par. 5, S. O. 133, Division of the Atlantic, which designated him as M. O. for the encampment (rifle practice) at Fisher's Island, N. Y.

Gorgas, H. C., Assistant-Surgeon. Leave of absence for one month, to take effect on the arrival of a medical officer to relieve him. Par. 2, S. O. 84, Headquarters Department of the Missouri, July 3, 1889.

Cherbonnier, Andrew V., Captain, Medical Storekeeper. Will, by direction of the Secretary of War, in addition to his present duties, take charge of the office and perform the duties of Acting Assistant Medical Purveyor in St. Louis, Missouri, during the absence of Captain George T. Beall, Medical torekeeper. Par. 2, S. O. 151, A. G. O., July 2, 1889.

Clinical Lecture.

SYRINGOMYELIA.

(A Clinical Lecture delivered at the Hospice de Bicêtre.)

BY M. DEJERINE.

(Reported by L. HARRISON METTLER, A.M., M.D., Lecturer on Mental and Nervous Diseases and Electro-therapeutics in the Medico-Chirurgical College of Philadelphia.)

THE Hospice de Bicêtre is in many respects the counterpart of Salpetriére, for being both a large hospital and infirmary for men (the Salpetriére being for women), it affords a magnificent opportunity for the clinical study of the nervous diseases. In a recent clinic, M. Déjerine, the attending chief physician, presented two marked cases of syringomyelia, a disease remarkable for the disassociation of certain sensory symptoms. As so few of the authorities give an exhaustive account of this affection, by reason of its comparatively recent recognition, I thought the readers of the TIMES AND REGISTER might be pleased with this well-known neurologist's account of it.

The first patient, a man, sixty-five years of age, had been in the Infirmary since 1868. He exhibited marked atrophy of the muscles, singularly limited to the superior extremities, and reproducing exactly what is known topographically as the Aran-Duchenne type. The thenar eminences on both sides were very much atrophied, giving the hands an apeish appearance. The interossei seemed less so, for the corresponding spaces were less pronounced and there was nothing of the main-de-griffe about the hand. In regard to the forearms, the muscles of the anterior region, particularly the flexors, were exceedingly atrophied. The same was true with those of the outer region, the long supinators and radii, while, on the other hand, the extensors were comparatively less atrophied. The muscles of the arm were also implicated, notably more so on the right than on the left. The deltoids, supra- and infra-spinatus muscles, were atrophied on both sides, especially so on the left. The great pectorals and trapezii were also diminished in size, and the superior internal angle of the scapula, being pushed up, projected over the posterior part of the supra clavicular triangle. The rhomboid of the left side could also be said to be atrophied, for when the patient carried his arm forward the internal border of the corresponding scapula was considerably separated from the trunk.

The lecturer then went on to say that the muscular atrophy in this case was really more marked than it seemed at first sight, because of the presence of a considerable amount of subcutaneous adipose tissue. There was very much deformity also of the superior part of the thorax; the cervical and superior dorsal parts of the column being strongly curved forward, the head sunk between the shoulders, the chin drawn strongly down towards the sternum, and the shoulders carried forward. Besides this cervico-dorsal condition of kyphosis, there existed a certain amount of scoliosis in the dorsal part of the column, the lateral

convexity being to the right and accompanied by a lateral deformity of the thorax, which bulged forward in its right half. As a result, of course, of all this atrophy, there was loss of functional power, the patient showing almost complete inability to use his hands and forearms. As to the movements of the arms and shoulders, they were extremely weak and limited. The other muscles of the body, face, and neck, lower half of the trunk and lower extremities, were absolutely normal, both in volume and functional power. Indeed, the patient could take long walks without being fatigued. The integrity of these muscles is a singular fact when it is remembered that forty years ago this muscular atrophy began, and that it has continued since and is still progressing, though very slowly, indeed, in the upper extremities.

The olecranon reflex was abolished on both sides. There was a certain amount of fibrillary contraction in the muscles of the upper limbs. The faradic and galvanic contractility was very much altered in the hand muscles, the flexors of the fingers, the infraspinous, and pectorals. In the trapezius and deltoid of the right side the existence of the reaction of degeneration was very clearly demonstrated. The skin of the hands and forearms was cold and cyanosed; at the level of the fingers and dorsal surface of the hand it was cracked, shining, and presented peculiar cicatrices, round and star-shaped, thick and traversed by small streaks. The phalanges of the fingers were enlarged, and there existed a hyperostosis about the size of a pigeon's egg, which, in 1852, Ricord diagnosed as non-syphilitic.

Using Weber's compass the lecturer next tested the sensibility of the whole cutaneous surface without finding anything abnormal, and this was the most remarkable part of the whole examination. As a still more ingenious and delicate test of the state of the sensibility M. Dejerine traced on the skin with a soft point the outlines of certain letters, but the patient recognized them immediately, though being blindfolded at the time. No matter what part of the body was touched the point was localized absolutely and correctly every time; the touch was furthermore done as lightly as possible. Hence the tactile sensibility was absolutely physiological.

Without proceeding to any further investigation of the sensibility, one would say that here we have simply a case of myelopathic progressive muscular atrophy, and such diagnoses have been erroneously made more than once. In fact the topography produced by the atrophy (the Aran-Duchenne type), the presence of the fibrillary contractions, the existence of the reaction of degeneration in some of the muscles, allowed an elimination here, in spite of the prolonged duration of the affection, of the progressive atrophic myopathy of which Landouzy and Dejerine had established the existence and frequency in their earlier works. The symptoms which this patient present belong, on the contrary, to myelopathic atrophy, and as he exhibits a certain amount of exaggeration of the patellar reflex, the diagnosis will rest between a simple chronic poliomyelitis or a poliomyelitis with sclerosis of the lateral fasciculi. But there is not a trace here of any bulbar phenomena, or, as the lecturer had shown before, bulbar paralysis is never met with in simple chronic poliomyelitis, and even to-day the existence of this one symptom is the best means of differentiating this affection from that with amyotrophic lateral sclerosis.

The further investigation of the state of the sensibility added to the diagnosis thus far attained, that his case was not simply a chronic poliomyelitis, for though the tactile sensibility remained perfect, that for pain and temperature was extremely altered in the upper extremities, superior half of the trunk and right half of the face. Over the whole extent of the corresponding cutaneous surface, the skin could be sharply pinched, pricked with a pin, or run completely through with a needle, without the patient complaining of any sense of pain. It seemed almsto cruel, and yet simple contact was the only thing preserved by the one being examined. In one of his clinics at the Salpetriére, Charcot also exhibited before the class and in his private room, to which he continuously admitted me, cases tested the same way and exhibiting the same phenomena. On the other hand, outside of the regions mentioned, that is to say, in the lower limbs, lower half of the trunk, left half of the face and mucous surface of the mouth, the sensibility to pain was preserved as in the normal state. In the next place the sensibility to heat was tested and found to be modified to an excessive degree. A flask containing water at the temperature of 90° or 95° could be passed over the skin in the analgesic regions without the least impression of heat being preserved. Although the hot water, was left in contact with the skin for some time, simple contact was the only perception noted. The skin could be burned without its being recognized, and this explains the nature of the cicatrices on the hands, which were nothing more nor less than the result of burns. The loss of sensibility to heat began even before the atrophy of the muscles had commenced.

It may be of interest here to state that Charcot employs a convenient form of instrument for testing the heat sensibility. It has the general appearance of a large surface thermometer, consisting of a kind of metallic cylinder about half an inch in diameter and about an inch and a half long, into one end of which is inserted a graduated thermometer from six to eight inches in length. The enlarged end of this is heated in a spirit lamp until the required degree of heat is registered by the thermometer and the patient touched with it. The advantage of this apparatus is at once apparent, as I had the opportunity to notice in certain cases where there was only a partial loss of thermic sensibility; for the patient could be repeatedly touched with the heated end as the temperature was falling, and the exact degree noted, at which there was no perception of the heat whatever. Comparisons also between different surfaces could by this means be far more accurately made. The sensibility to cold was as much altered in the present case as that to heat, for there was no other response save that of simple contact when a piece of ice was held, even for a long time, against the surfaces mentioned. In a word then there was here an absolute thermo-anæsthesia

corresponding exactly topographically with the analgesia. Over the rest of the cutaneous surface, however, the sensibility, both to temperature and pain, remained perfectly normal. The muscular sense, by which is meant the notion one has of the position of his limbs, the special senses, the sphincters of the patient were all perfectly normal. To sum up then, the first case has as its special symptoms, progressive muscular atrophy of forty years development, and certain other troubles disassociated from sensibility; namely, preservation of the tactile sensibility over the whole cutaneous surface, coinciding with the analgesia and an absolute thermo-anæsthesia, located in the right half of the face, the upper half of the trunk and the upper extremities; that is to say in a region which, with the exception of the right half of the face (the muscular apparatus of which remained intact), corresponds to those parts of the skin covering the atrophied muscles.

The second case which the lecturer then introduced was a man, fifty-four years of age, who had only come into M. Déjerine's service the last year. Here the atrophy began thirty years ago in the hands. I will not weary the reader with further further particulars about the history and symptomatology of this case as it resembled the first almost identically, excepting that the reactions of degeneration, even when partial, were imperfect, the electric contractility being diminished only quantitatively. The olecranon reflex was almost nil, while that of the patella was exaggerated. Here, as in the former case, we had the existence of certain phenomena disassociated from sensibility, namely an absolute integrity of the tactile sensibility over the whole surface of the body, corresponding with a profound alteration of the sensibility to pain and heat in the upper extremities, left half of the neck, and inferior half of the face of same side. When the water was heated to 90° and the flask allowed to remain on the part about twenty seconds, the patient said he felt a very slight degree of warmth, and was quite able to bear it much longer, though had he done so, vesication of the skin would have been the result.

Proceeding then to the further study of the affection thus presented, M. Déjerine said that ever since the work of Ollivier of Angers, it has been known as syringomyelia (the spinal marrow being hollowed out in the form of a tube). There are three distinct periods in its history. The first exhibited most prominently the macroscopic changes which especially awakened the curiosity of the anatomo-pathologists, such as Morgagni, Portal, Senac, Andral Hutin, Nonat, Leuhossek. In the second period, certain clinical observations rendered more complete the anatomo pathological study of the first. In 1862 M. Lancereaux reported, under the name of hypertrophy of the spinal ependyma, a case affected with certain derangements of mobility and sensibility with a deformity of the vertebral column, which at the autopsy discovered the center of the spinal cord occupied throughout its entire length by a fibrous column hollowed with cystic cavities. The same year W. Gull published an analogous case, which was shortly followed by those of L. Meyer, O. Schüppel, Steudener, Hallopeau, Westphal, Leyden, Roth, Schultze, Kahler and Pick, Strümpell and Wipham. At this time neither the s mptomatology nor the possibility of diagnosing this disease was established; it simply remained a pathological curiosity. In the third period, which dates only from the year 1882, syringomyelia takes its place among the class of spinal cord diseases. Thanks to the more minute study of the troubles of sensibility, thanks to the new anatomo-pathological revelations, this disease has at last found its definite place in nosology, as shown by the recent works of Kahler, Furstner and Zacher, Freud, F. Schultze and W. Roth (of Moscow). It is to these authors in fact that we owe our knowledge of the troubles of sensibility, particularly of the thermic sense, so characteristic of this affection, which troubles coexisting with other symptoms have permitted MM. Debove and Déjerine to present to one of the recent meetings of the Sociéte Médicale des Hopitaux, each a case of this strange disease, of which the two cases introduced are new examples.

The diagnosis of syringomyelia is to-day possible in the vast majority of cases. Here are the symptoms and lesions which characterize it:

Syringomyelia generally commences in youth or adult age, between the years fifteen and twenty-five as a mean, according to the most recent statistics. The beginning is insidious, manifesting itself by duel pains and aches in the cervical and cervico-brachial region. At other times the patients complain of weakness in the upper limbs, with a rapid sensation of fatigue. Occasionally the changes in the thermic sense begin the affection, as in the first case presented to-day, who, during military service, and being consequently at that period still very strong and vigorous, burnt himself frequently without knowing it; but this phenomenon is rare so early in the disease. Soon the muscular atrophy begins to make its appearance, starting almost always in those muscles innervated through the cervical enlargement and affecting the topographical distribution of the so-called Aran-Duchenne type. Generally this atrophy progresses very slowly and, as in poliomyelitis chronica, begins in the smaller muscles of the hands, which assume an apeish appearance, often that of the main-en-griffe. This atrophy gradually involves the muscles of the upper extremities and thorax. Most often it is very regularly symmetrical as in chronic poliomyelitis, but its evolution is much slower than in the latter disease.

The affected muscles exhibit the fibrillary contractions and sometimes one meets, as in the first case, the reaction of partial degeneration. The olecranon reflexes are abolished, the atrophied members flaccid, and the functional power diminished pari passu with the atrophy. In the vast number of cases, the muscles of the face and lower limbs remain intact. And, finally, the cyanosis of the ends of the atrophied extremities should be carefully noted.

The tests for the sensibility must be made methodically and with extreme care, for in syringomyelia the troubles of sensibility are associated, and it is this peculiar phenomenon that enables us during life to recognize the disease with certainty. The tactile

sensibility is preserved. The sense of pressure and the muscular sense are also preserved in the two cases before us, and there is thus a kind of notion of the position of the limbs.

On the other hand, the thermic sense is profoundly altered in syringomyelia and in general from the very earliest periods of the disease. In one of Prof. Charcot's cases which I saw, this alteration of the thermic sense was a most remarkable phenomenon. The thermo-anæsthetic area could be outlined with quite sharp limits, for as soon as the piece of ice or heated thermometer-like instrument crossed the line into the sensitive area, the patient would give a violent jump, being unable to endure the extreme cold or heat. The present patients were unable to distinguish a temperature ranging between 10°, 90°, 100°, and even higher. So they frequently burnt themselves unknowingly, and this is one of the reasons, not the only one, why in these cases we so often meet with cicatrices about the fingers and hands. Finally, the sensibility to cold is altered in syringomyelia as well as that to heat.

The sensibility to pain is very rarely intact. W. Roth, however, has seen some cases in which only thermic anæsthesia and muscular atrophy existed. Most frequently the analgesia proceeds along with the thermo-anæsthesia, as in these two cases, which have lost at the same time both the pain and heat sensibility in corresponding regions of the skin. But the analgesia cannot be always so clearly indicated as in these two cases. Most frequently the analgesia and thermo-anæsthesia advance together and occupy the same localities of the skin. Thermic anæsthesia alone is very rarely observed.

The loss of sensibility to pain and heat is not limited to small patches; in fact, it is found to involve large areas of the cutaneous surface, as in the above two cases. The skin of the face, as here illustrated, does sometimes participate, and the mucous surfaces likewise may be involved as in a case reported by Schultze. Finally, in some rare cases, the sensibility phenomena may assume the hemiplegic type.

Such are the fundamental symptoms of syringomyelia, added to others, some of which are constant, others more or less frequent. Among the former may be cited the scoliosis of the vertebral column; among the latter the frequency of trophic phenomena of various kinds, hyperkeratinisations, bullæ, broken conditions of the skin, fragility of the bones, swelling of the epiphyses, articular lesions, panaris, and phalangeal disarrangements. Finally, there is sometimes observed an increase of perspiration in the anæsthetic regions. Muscular atrophy, scoliosis, frequent trophic disturbances of the tactile sensibility, with marked alteration of sensibility to pain and heat are the principal symptoms of syringomyelia. But in some cases, rarely in the others, the Aran-Duchenne type may be wanting, just the same as in certain cases the preservation of the tactile sensibility may in the end itself disappear; this latter event is only observed in very old cases, and even then it is very exceptional. The two examples which we have been studying are the proof of this. In one the affection has been developing for forty years, in the other thirty. Now, in both, the tactile sensibility is intact. There is nothing surprising in the long duration of this disease, syringomyelia being an affection developing very slowly and progressively, and being able at times to stop in its advance without, so far as we know at present, being able to retrocede.

The pathological anatomy of the affection is to-day well known. It is the result, not of an inflammation of the cord, a myelitis, but of a neoplasm, a glioma of the spinal marrow. The lesion (and here some specimens were exhibited, prepared by M. Barth) is located in the center of the cord, and occupies its entire length. At certain points the neoplasm can be easily separated from the nervous substance to which it is united only by the weakest attachments; at other points the adhesions are more intimate. The central glioma, formed of cells closely packed one aginst the other, often exhibits lacunæ, the pathogeny of which is still unsettled, and whose walls are lined with a fibrous coating. This glioma, developing excentrically, presses upon the spinal cord substance and produces consecutively the symptoms that have just been noted. The lesion is almost always more marked in the cervical region than in the rest of the cord. This explains why the muscular atrophy and phenomena of sensibility are seated so often in the upper extremities. The glioma may at times push the lateral fasciculi into the gray or white substance. In such cases, relatively uncommon, the ordinary symptomatology is much modified, and we have the appearance of the symptoms of spasmodic tabes in the inferior extremities; and these are exceptional cases.

It is necessary then to remember that the symptoms of syringomyelia are the result of a medullary compression excited from within outward by a neoplasm, a central glioma of the spinal cord. This compression explains to us the disassociation of the phenomena of sensibility so characteristic of this affection. In fact, the posterior columns by which tactile impressions are transmitted (Schiff) escape this compression, which is not the case, however, in regard to the central gray substance, the tract for the transmission of impressions of heat and pain (Brown-Séquard). The muscular atrophy must still be attributed to the compression of the anterior cornua.

The diagnosis of syringomyelia is easy, when, as is the rule, the white substance is not invaded by the glioma. It is distinguished from myelopathic muscular atrophy, from progressive atrophic myopathy, and from amyotrophic lateral sclerosis by its sensitive phenomena. Hypertrophic cervical pachymeningitis is distinguished by its pains, stiffness of the neck, contractness, the manner in which the atrophic paralysis develops, the special attitude of the hands, and the absence of troubles of disassociated sensibility.

There remain then only Mowan's disease and lepra. In the first place, Mowan's disease very closely resembles syringomyelia, the muscular atrophy and the scoliosis are the same; the thermic sense and sensibility to pain are also extremely altered; in this affection there exist also certain trophic disturbances, among others the panaris and phalangeal disarrangements; finally the development of this disease is also

extremely slow. But in almost all of Mowan's cases the tactile sensibility was altered along with that for pain and heat. Furthermore, it has been shown by a recent autopsy made by MM. Gambault and Reboul that Mowan's disease is characterized, anatomically, by a peripheral neuritis, very intense, and occurring coincidently with a very slight lesion of the posterior columns of the cord.

This disease, then, is classed among the peripheral neurites, and this is not surprising when one remembers that here no phenomena of disassociated sensibility have been established. As for the next, there is no proof that Mowan's disease has always the same pathogeny, and if the peripheral neuritis perfectly explains the great majority of the cases observed by this author, some among them may turn out to be syringomyelia. M. Déjerine here said he alluded to a case reported by this distinguished physician in which the preservation of the sense of touch was noted.

In anæsthetic lepra a clinical picture is seen very analogous to that of syringomyelia: Aran-Duchenne type of muscular atrophy, sensitive disturbances, trophic disturbances, with frequent mutilations, in a word, all of the symptoms analogous to those of syringomyelia; but the differential diagnosis is made from the knowledge of the existence of the leprous affection, and by the fact that almost always in nervous lepra the tactile is altered, along with the other varieties of sensibility. In very rare cases (the cases of Rosenbach) in which has been established at the level of the maculæ the preservation of touch, with alteration of the sensibility to pain and temperature, the leprous neuritis could still be very clearly recognized by the following signs: The anæsthetic and thermo-anæsthetic zones were irregularly distributed in patches, and the transition from the anæsthetic to the healthy areas was very abruptly marked. This is just the opposite of what obtains in syringomyelia where the zones of analgesia and thermo-anæsthesia occupy broad surfaces.

In finishing with the diagnosis of syringomyelia, M. Déjerine cautioned his hearers in regard to being misled by certain sensitive disturbances sometimes occurring in cases of myopathic or myelopathic atrophy, and likewise in a neurosis of the nature of toxic hysteria. And yet I am tempted to mention just in this connection a case of real hysteria, which Charcot brought before us in one of his clinics, and which simulated to a remarkable degree either of the two cases of syringomyelia cited at the head of this paper. It was simply astonishing how closely the affected signs corresponded, how nearly the symptoms (excepting the atrophy and spinal deformity) agreed, and what amount of sensibility the man exhibited when tested in the usual way with pricks, heat, and cold.

In quite an extensive lecture afterwards, Prof. Charcot cautioned his hearers against confounding two such dissimilar affections as syringomyelia and hysteria. The history of the case, particularly in the latter, has always a great weight.

The etiology of syringomyelia is still obscure, but if we consider the nature of the process, which is a neoplasia, the frequency of its development in youth, the slowness of its evolution, it is more than probable that here we have a medullary lesion for its starting-point, some developmental anomaly of the elements composing the central gray substance of the spinal cord.

DIETETICS.

IN ITS RELATION TO DISEASE.

(Delivered at City Hospital, February 1, 1889.)

By J. T. McLAUGHLIN, M.D.,
SPRINGFIELD, O.

LECTURE I.

INTRODUCTORY TO THE SUBJECT.

AMIDST the claims and duties of my practice, it is impossible to do justice to the comprehensive subject assigned to me, without giving it somewhat fragmentarily and in separate lectures.

Dietetics is that part of medical science which relates to diet or food. In the assignment of the subject to me, I am restricted to the diet or food proper for the sick and the convalescent.

But before discussing the practical application of the dietetics in disease, it will be advisable, as an introductory, to consider briefly a number of points.

I. The growing importance of Dietetics, and the practical interest taken in it by the medical profession. This is sufficiently indicated by the patent facts, that we have medical journals exclusively devoted to the subject; that we have the most advanced students making it a specialty in their studies and publications; and that foods of various kinds, suggested by experience and formulated by chemical analysis, are so largely patronized by eminent practitioners.

II. A reader of historical medicine will notice the remarkable advance made by the moderns in this respect. This is shown in several ways.

1. By making it more and more a practical and essential branch of knowledge, as evidenced by the space given to it in medical works.

2. By the fact, corroborated by experience, that physicians are more deeply impressed than ever, that in nearly all cases of disease the proper supply of nutrients is of primary importance. Indeed, in many cases diet is far more efficacious than drugs.

3. The extended researches of organic chemistry and physiology have given dietetics a proportionate advance. For the former gives us accurate knowledge of the elements of food and their value; the latter enables us the more accurately to use those elements and reap the desired benefit.

4. This progress is seen by simply observing that nutriment, at one time strenuously forbidden, is now not only allowed, but even encouraged. This prohibitory period extended over the time when water, so craved by the fever-stricken patient, was rigorously disallowed.

III. This advance, a source of gratification to the intelligent student, has proven of great benefit.

1. It has materially lessened the suffering of the patient, as, *e.g.*, in allaying his thirst and in providing food adapted to his condition.

2. It has proven itself a health restorer, giving just what was needed under certain conditions of disease and convalescence.

3. It has clearly shown that food, in many cases, has been the most effective remedial agent that can be employed.

4. It has also by its revelations of the health-restoring resources of alimentation, indicated more clearly the use and efficiency of drugs or medicines.

5. Not only the profession, but many intelligent families, having gained confidence by the success attending the treatment of their maladies, are experiencing these benefits.

6. It has especially been subservient in reducing the fearful mortality of children under one year of age. Specialists on this point declare that, in the malnutrition and diseases incident to infancy, the chief reliance for remedial agency must be on alimentation. If this is kept in view, the majority of cases will be relieved, and the mortality be greatly diminished. No practitioner but comes in contact constantly with cases in which dietetics must suggest the curative or preservative.

IV. A knowledge of the essential ingredients of food is requisite. Chemistry has given the component elements of our food products, and every physician has in his library the tabular statements of these constituents, and of their relative value. A reasonable acquaintance with such tables is, of course, taken for granted.

V. In the application of our knowledge, we encounter, now and then, peculiarities that remain unsolved, viz., what are called idiosyncrasies, *i.e.*, personal constitutional peculiarities which will cause one person to reject food that others can use with impunity, which one stomach loathes and another accepts with avidity and benefit. Medical works allude to such cases, and practitioners occasionally come across them.

Many suppose that a certain normal condition is the cause; others, that it arises from a vitiated condition of the digestive organs, superinduced by some hidden disease. The opinion that this variation results naturally, just as taste differs in individuals, is probably the correct one.

Now, this suggests two reflections of practical importance, viz.:

1. In dietetics the physician should be guarded against such cases of idiosyncrasy, in order to secure the best results. Thus to illustrate my meaning: food that has a decided laxative tendency in one, may have an equally decided tendency to costiveness in another. True, such are exceptional cases, but for this very reason special attention ought to be given to them.

2. May not this feature of idiosyncrasy be the foundation, in some cases, of the utter failure of certain medicines in their action, which benefit the large majority? Dietetics shows that it exists, and this variation may be as potent in drugs as it is in food.

VI. In dietetics, generally considered as applicable to health and sickness, climate has its decided influence; the animal oils of the frigid zone giving place to the vegetable oils of the torrid. Even the seasons of the temperate zone suggest, as nature evidences in its supply of food, a variation of diet suitable to the varied conditions of temperature, etc., under which we live.

VII. We must, in the application of dietetics, be mainly guided by the power possessed of digestion and assimilation. This greatly varies, not only in infancy, childhood, manhood, and old age, but also in the form of disease encountered. Food highly beneficial in one case would be positively and uniformly injurious in another.

Great injury is sometimes done, and fatal relapses are occasioned by the use of food utterly unfitted for the power of the patient or the convalescent. No physician but has had experience in this direction, and this experience has enforced the expediency of due caution.

Without due digestion there can be no health, and no restoration to health, and, therefore, to this very point, as the great essential factor, the intelligent physician's attention will be specially directed, and the power of the patient be duly considered. This, in some instances, requires time and patience, and even trial, seeing that the processes of digestion are complex, and that, for yet unexplained reasons, variations or modifications also exist. If we are to credit the experience of the past, these things are self-evident:

1. That without some measure of digestive power possessed, and the administration of food adapted to the same, it is hopeless to expect health.

2. That when the digestive processes are weakened and impaired, and food is taken which the digestive organs are unequal to utilize, it is vain to expect improvement, no matter what system of modification is resorted to, so long as the practice is continued.

3. That the use of injudicious food by sick and convalescing persons has laid, owing to the weakened condition, the foundation of disease of the digestive organs, from which they suffer for years.

4. But more than this. The highest medical testimony traces diseases, once not even suspected to be thus connected, as derived from disordered digestion, such as gout, rheumatism, neurotic and skin affections and other maladies. Sound judgment teaches, that if such diseases are to be successfully treated, the digestive organs, and the food that they can properly digest, must be the main study of the physician.

VIII. It is generally acknowledged in dietetics that food ought to be adapted to the occupation. The same principle must apply to organic diseases and to the convalescent. My meaning is this: food, within the limits already defined, may be allowed to a patient engaged in manual labor, that would be entirely unsuitable and injurious to one not thus employed.

IX. Of course, a professional and scientific knowledge of the organs and the processes by which the human frame is nourished, is taken for granted as of primary importance, but such knowledge may exist

without a practical application of it to each individual case. Thus, *e. g.*, a person troubled with dyspepsia comes under the treatment for another disease; now it would be a grave mistake to confine our consideration of his case to the latter and ignore the former. Each should receive the full benefit that a physician's knowledge suggests, and this is never completely done when the cautions and directions required in certain cases are neglected. Delicate and impaired constitutions, in this respect, require constant watchfulness, and without this continued application of dietetical knowledge cannot be restored to vigor and health.

X. This suggests the fundamental statement, that the nature of the disease will dictate the food that is to be given. Leaving the details for other lectures, it may be said, in a general way, that in some diseases, as acute fevers, and where the alimentary canal is seriously affected, the recovery of the patient chiefly depends on the quality and the quantity of food taken into the system. In diseases that greatly impoverish the blood, convalescence is materially aided by suggesting and using food that, while easy of digestion, "builds up," or supplies the required constituents.

XI. The ordinary nutritive demand to supply the waste of healthy action has been averaged in our medical works, and the sum total in a year's time is simply amazing. The comfort, vigor, and efficiency of life depends upon the waste of the system being satisfactorily supplied, and any deficiency will result in injury. Now, if this be true in a healthy condition, much more is this enforced when disease increases this waste. Drugs, however excellent in their use, cannot, and were not intended to, supply this waste. Dietetics alone meets the requirements, and is effective in proportion to an intelligent and well considered use.

XII. We may say, also, that in disease especially the effectiveness depends upon the proper cookery or preparing of the food. Digestibility and nutritiveness of food may be utterly neutralized by an ignorant cook. The highest medical authorities insist upon it, that the intelligent physician should have a proper conception of the preparation of food, in order to adapt it to the condition and necessities of the patient. Even in the comparatively simple matter of gruels, or of concentrated nourishment, a physician's watchfulness will be inspired by the crisis of a serious acute case.

A doctor frequently finds, especially in fevers like the typhoid, that the greatest impediment that he meets is the improper cooking for the sick; and, on the other hand, his most serviceable diet comes from a good cook. If it is true that the former has ruined the health of multitudes, it is likewise true that it has crippled the efforts of physicians, counteracted the intended action of medicine, brought on dangerous relapses, and sent its thousands to the grave.

We do not overrate this feature, and are gratified to find that this very estimate is most prominently brought out in modern medical science, not only in books and publications specially devoted to the diet of the sick, but in our standard works. Compare, for example, the standards of twenty-five years ago with the works of to-day, and we find that diet, which was but incidentally introduced in the former, is made a subject of leading consideration in the latter even, in many instances, descending to the minutia of preparation to ensure its effectiveness. For this improvement we are mainly indebted to the progress made in organic chemistry and in physiology.

While medicinal therapeutics has advanced, that of dietetics has been comparatively greater. So that now a "medicine man" cannot be regarded as such, because he is prepared to give pills, powders, and lotions according to formulas provided, unless he also realizes, as of the utmost practical value, that a carefully selected and prepared diet is essential to impart the strength requisite to give even medication its efficiency and overcome disease. The most able professors and teachers of all schools assert that in many chronic diseases, the chief reliance must be placed in dietetics.

XIII. In order to avoid undue length, let me conclude with the following suggestive caution. If the application of dietetics is to be beneficial, the physician must be guarded in the administration of his medicines, so as not to interfere with the digestive processes. In stomach, liver, kidney, and other troubles, the medicine given may be highly injurious, retarding and impairing the action of the gastric juice, or tending to undue secretions of the bile, pancreas, etc.

I am fully aware of the fact that this introduces a subject, upon which a variety of opinions exist, but that danger to the patient and ineffectual action of medicine arise from this very cause is a point that no one contradicts. Warnings and directions in this line come from the ablest students of medicine. Careful observation, as well as a better understanding of chemical laws, have demonstrated the wisdom of due caution in the administration of medicine, so as not to interfere with the radically needed powers of digestion and assimilation.

But recently the *British Medical Journal* had an article on The Proper Time for the Administration of Acids, Alkalies, etc., so as to harmonize the same with their relation to dietetics. The statement is of such practical value, that I take the liberty of quoting the same.

"Alkalies should be given before food. Iodine and iodides should be given on an empty stomach, when they rapidly diffuse into the blood. If given during digestion, the acids and starch alter and weaken their action. Acids, as a rule, should be given between the digestive acts, because the mucous membrane of the stomach is in a favorable condition for the diffusion of the acid into the blood. Acids may be given before food, when prescribed to check the excessive formation of the acids of the gastric juice. By giving it before meals, you check the osmosis stomachward of the acid-forming materials. Irritating and dangerous drugs should be given directly after food, such as the salts of arsenic, copper, zinc, and iron, except where local conditions require their administration in small doses before food. Oxide and nitrate of silver should be given after the process

of digestion has ended; if given during food, chemical reactions destroy or impair their special attributes, and defeat the object for which they were prescribed. Metallic salts, especially corrosive sublimate, also tannin and pure alcohol, impair the digestive power of the active principle of the gastric juice, so should appear in the stomach during its period of inactivity. Malt extracts, cod-liver oil, phosphates, etc., should be given with or directly after food, so that they enter the blood with the products of digestion."

This simply illustrates the idea intended, viz., that dietetics and the administration of medicine should work together in harmony, the one supporting and dividing the other. This, of course, suggests three considerations, which it is sufficient to state.

1. The proper time for administering medicines, so as not to interfere with digestion of food; as well as the withholding of such in certain conditions.

2. The selection of food that may be least effected by the action of drugs.

3. The efficiency of medication itself is greatly enhanced by due attention to the use of proper drugs, at the proper time, in connection with proper food.

VINEGAR AND VINEGAR YEASTS.

(Read before the Committee on Dietetics.)

By E. & J. A. CUTTER,
NEW YORK.

THERE is an old saying that one man's meat is another's poison. While this is true it is also true that the way in which we use our foods, makes all the difference between life and death, health and sickness. For example, to give a cup of cold water is an act of hospitality to health, but to make a guest drink a quart of ice water, especially if that person is heated or overheated has caused death. Vinegar (vin—wine, aign—sour) or sour wine, is no exception to this rule. In 1858 I sat in the reception room of the Galt House, Ky. By my side were two gentlemen, evidently residents of Louisville, taking a "club room chat." They talked so as to be heard. "By the way," said one, "did you hear how Dr. Gross cured Mr. Jones?" "No," said the other. "Well," said the first, "he went to New York and all around in this country to the best doctors. He also went to Europe and consulted the eminent men in the profession, but he returned not benefited. When he got home he went to Dr. Gross and he cured him. It was a curious, simple prescription, I don't think you can guess what it was, so I will tell you. It was '*pickles.*'" Some twenty years later, the elder Dr. Gross told the writer this was true, and it was a great mistake of doctors that they did not use foods more as medicines. *Per contra* a small glass of vinegar daily used, killed a young lady by inducing the deposit of tubercle in the lobes of the lungs.—*London Medical Gazette*, vol. ii, 1838.

It also, in excess, causes thrombi in the blood, constipation, wind, diarrhœa, and cough, flushing of head, watery eyes, to say no more. See the Relation of Food and Disease, J. H. Salisbury, M.D., LL.D. Vail & Co., 1888, New York.

This is a sad accusation and needs to be impressed, but only a few points can be made here.

Vinegar or acetic acid is formed in the alimentary canal by the fermentation of carbo-hydrate food. It is produced by the action of a plant called the vinegar plant or mycoderma aceti. The kinship of this vinegar plant is very close to the alcohol plant, saccharomyces cerevisiæ. This is seen clearly in bread making, which has been raised by yeast. If the process, as every cook knows, is not properly managed the bread will become sour from the vinegar formed along with the carbon dioxide gas, alcohol, and water. Just this process occurs in the stomach when the farinaceous food sours. So that it may be said when one eats foods that undergo the alcoholic and vinegar fermentation in the stomach, that persons make a brewing of alcohol and vinegar therein. How does this process occur? If you do as Pasteur did, take the bloom of grape and put it under the microscope, you will find as he found, and I have found, especially in grapes long kept, the alcohol and vinegar plant, present in quantity. In other words these minute plants are present in connection with our vegetable foods, put there so that in case the foods are not used they produce a change of state back again to the elements whence they were made. If it were not so, they would accumulate and the world would become a vast charnel house of old organic dead matters.

Now how does vinegar in excess cause disease? In two ways. First, by its chemical action on the substances found in the human body. Second, by the presence of the vinegar yeast itself. Perhaps this division is too arbitrary, for you cannot have the plant itself in action without the acid, to wit, vinegar, but perhaps the hearers will pardon the division for the sake of clearness.

First, by chemical action, which interferes with the process of life in the epithelium, by burning thereby making the tissues partially paralysed and thus thickening them and causing them to develop in a state of low vitality, by interfering with the protoplasm of the cell tissues as most microscopists know, and coagulating the fibrin.

This is seen in a remarkable way in rheumatic blood, the fibrin filaments made large and coarse attract others and are aggregated with filaments and skeins of great comparative size, forming thrombi and emboli, which in turn produce the diseases called after them.

Second, by the presence of the vinegar plant in the blood. Sometimes the epithelium don't let the yeast get into the blood and the work of disease is confined to the bowels. Hence we have chronic diarrhœa or consumption of the bowels, attended with colloid discharges which sometimes almost exactly resemble the contents of ovarian or goitrous tumors. But when the epithelia of the bowels get drunk with alcohol or paralysed by the vinegar, they then let the vinegar yeast go through them and get into the blood, where they float about the stream, and are easily detected by the microscope.

If the vinegar becomes detained in the capillaries of any organ, they go on growing, producing vinegar, and the resultant of this action on the organism is what we call tubercle. Along with the alcoholic

and vinegar yeast are found bacteria. For about thirty years the botanists were divided in opinion as to their significance. Some said they were an accidental accompaniment, others said that they were a part of the biological phases of the vegetation.

The latter now prevail, as Dr. Koch has succeeded in cultivating them and propagating them as such in their baby stages of development, and has shown them to have a causal relation to the tubercle.

For this work the world has been profoundly grateful, and the writer accords the meed also, but he prefers to adhere to the vinegar yeast as the prime cause, on the ground that not only has tuberculous consumption been produced (and verified by autopsies) by feeding animals on food containing vinegar yeast, which has been traced to the bowels, next to the blood and next to the lungs, but also by removing the vinegar yeast from the blood by the very simple expedient of stopping the food, which feeds the vinegar plant, giving a food that does not have that fermentation, giving medicine to oil the machine, and nature does the cure.

And there are *cures*, I published as such, in the Transactions of this Society for 1880. Have cured others since.

The outcome of this is that vinegar should be used with caution. The writer prefers what he can call by no better name, the tartaric acid vinegar, made from wine of our native or foreign grapes. He hopes that this source of a true more healthy vinegar will not be overlooked, and that caterers will serve this in place of the acetic acid vinegar, which is so dangerous in excess. The process of making this *wine* vinegar does not differ from that of cider vinegar, and when grapes are sold at twenty dollars a ton, this tartaric acid vinegar ought to be cheap. This paper should be accompanied by the lantern illustration of the alcoholic and vinegar yeasts in and out of the blood, which give more pertinence to the observation and are at the service of this Committee.

The practical deduction to be made is to avoid the excessive use of substances producing vinegar in the system.

The Polyclinic.

PHILADELPHIA HOSPITAL.

WHOOPING-COUGH.

THIS young child presents a marked case of whooping-cough. It has twelve paroxysms of coughing in twenty-four hours. It is a condition that is difficult to make out at first; and at the beginning it is nothing more or less than a catarrh. There are conditions of mild bronchial irritation; slight mucous râles; no dulness on percussion. As the disease approaches there will be a spasmodic cough. The duration varies from two weeks to three months, or longer. At all events, you are disposed to look upon it as a disease of children, but adults get it also. There may be annoying complications, such as acute or capillary bronchitis, or even pneumonia. Treat all bronchial irritations as from any other cause. Many remedies have been used, but in the first stages a mixture of potassii chloras, syrup of ipecac, syrup, water and a little paregoric, is all that is necessary. As it advances the more specific forms of treatment come in. Tincture of belladonna is used to-day to control the cough to a certain extent, but it does not do it absolutely; but still is a good thing to use. I begin with min. 1–3 of tincture of belladonna ter die, and increase it to tolerance, if there seems to be any impression on the number of paroxysms. This will be as satisfactory a plan as you can adopt. Of late years it has been looked on as due to a specific cause, and inhalations of carbolic acid have been used; but I prefer Dobell's solution as an inhalation, from an atomizer, every three or four hours, or as the paroxysms require. In treating all cases of this kind, I confine myself to this treatment. Isolate your patients and disinfect. There may be a rupture of some vessel during a paroxysm, while vomiting is very common.

—*Stryker.*

STRANGULATED HERNIA.

Steinbach brought in a man who had an inguinal hernia which the man could reduce himself; but thirty-six hours ago, while at stool, the tumor descended with pain and the patient could not reduce it. His scrotum began to swell and became inflamed, and all efforts at reduction failed. Patient was etherized, but still it could not be reduced, so an incision two inches in length was made through the scrotum and the tumor exposed. Several ounces of serous fluid escaped, and then the ring was nicked with a dull knife and reduction attempted without success, on account of a large mass of omentum. Ligatures were passed around the omentum and about six inches was cut from it; and, after breaking up quite a number of adhesions, the protruding gut was replaced. The parts were dressed antiseptically. He grew worse and died on the fifth day after the operation.

COMMINUTED FRACTURE OF FEMUR.

Ransley showed an old man who had a comminuted fracture of the shaft of the femur, in which the bone was broken into four separate fragments. Several days ago the leg was dressed with a fracture-box and pulley extension on an inclined plane. Examination showed no effort on nature's part for union. Will continue this treatment for a short time and then encase the leg in a plaster dressing. Plaster dressings are objectionable, as the parts cannot be opened up readily to make examinations or to note progress.

EXOPHTHALMIC GOITRE.

Woman, aged forty-seven years; Irish domestic; father died of phthisis at forty-five years; fifteen years ago had rheumatism and rheumatic fever, and has since had another attack. She has been readmitted to the Hospital twenty-nine times; is much emaciated and has much pigmentation of the skin; has the pterygoid or alar chest; infra- and supra-clavicular depression; an overacting and hypertrophied heart; eyes very prominent and distinct; enlarged thyroid gland, which is soft and distinctly nodulated; rapid and distinct pulsations of the vessels at the root of

the neck. She is suffering from exophthalmic goitre or Graves' disease. Short systolic murmur at aortic orifice; also a lesion of mitral valve. Heart hypertrophied and dilated; liver and spleen slightly enlarged, due to ague, and in fact, gentlemen, she is a regular pathological store-house. Prognosis is favorable as regards life, but not a cure. The exopthalmos can be lessened. She must be relieved from all anxiety and worry; and to accomplish this she will be put in bed for three weeks in the recumbent posture. Abundant and nutritious food and good hygiene. Quinine, in gr. x–xv dose per day, has been used to good effect. Digitalis and aconite are distinctly contra-indicated in this case. I purpose giving two remedies that have much to recommend themselves. First, tincture cannabis indicæ, min. x, three times a day, pushed to tolerance. It is given as it has a curious sedative effect, unattended by unfortunate results. It is one of the best remedies against intestinal catarrh, as it quiets peristalsis and allows the formation of fecal masses, and thus controls diarrhœa. At the same time, I will give nitroglycerin (1 per cent. sol.) min. iij., three times a day to cause the peripheral vascular system to dilate and promote better nutrition to those parts that most need it. Will also give her inhalations of oxygen gas, two parts, and nitrous oxide, one part, three times a day.—*Wilson.*

OTORRHŒA.

Stryker says this trouble may come in young children from any increase of cold to which a child is exposed, or may be due to the presence of a foreign body, such as a grain of corn and other articles. Treatment consists in removing all foreign substances and washing with warm water. If this will not give relief use some anodyne, as a 4 per cent. solution of cocaine introduced with a pencil of hair. Never stop up the external ear, as it will block the secretions, cause loss of hearing, or rupture of the membrane. If it does not yield to this treatment use boracic acid in powder as an insufflation. If still more intractable, use a two-grain solution of sulphate of zinc or a half-grain solution of argenti nitras.

POST-MORTEM SPECIMEN.

Walker reported the case of a man who had a peculiar heart murmur, which commenced after the second sound and would stop before the first sound. In 95 per cent. of these cases this murmur means an aortic regurgitation. Murmur is diastolic and was heard over the apex for a limited area; no trip-hammer pulse. Case was diagnosed as an obstructing lesion at the mitral orifice. Pulmonary fulness and hæmoptysis. Man died, and post mortem showed the left side of heart somewhat thickened; mitral orifice funnel-shaped, and would scarce admit the tip of the little finger.

COLOTOMY.

This man was admitted six weeks ago, and a stricture of the rectum was suspected. On examination extensive infiltration was found around the bladder, and a hard mass of a cancerous character encircled the rectum. He experienced great difficulty in movement of his bowels, and was losing ground rapidly. In order to prolong life an operation for colotomy was done. Midway between the twelfth rib and the crest of the ilium, and three inches from the spine, on the left side, an incision three inches in length was made transversely through the structures until the colon could be hooked up with a needle. An incision was made into the gut and stitched to the skin—not the muscles, as they contract spasmodically—and an artificial anus was made. Wound was dressed with all antiseptic precautions and patient put to bed and given liquid diet. Two weeks later he was again brought before the class and was doing well. The new opening had healed nicely, and was provided with something closely allied to a sphincter, and he can to a certain extent control the escape of feces. The mucous membrane looks healthy. He will soon be about again. The orifice is circular, and has the appearance of a healthy anus.—*Steinbach.*

Paris Letter.

TREATMENT OF ENDOMETRITIS.

DR. DUMONTPALLIER, who fell heir to Dr. Gallard's important service of women's diseases at the Hôtel Dieu after the last-named doctor's death, has just given a new form of treatment for endometritis, by the use of chloride of zinc pencils, that are carried up into the interior of the uterus. One hundred and twenty cases have been treated with great success. The vagina is first of all washed with a carbolic acid solution of 1–100. The hysterometer is also carefully rendered aseptic and introduced to get the direction of the uterine cavity. Having done this, the chloride of zinc pencil (which is pliable enough to bend in any direction) is then passed up until it touches the base of the uterus. In some cases a small vaginal tampon is then put in to keep it in place, but this is not necessary. Another washing of the vagina is then made so that all trace of the caustic is taken away from it. The results of this treatment were remarkable. In metritis, of hemorrhagic nature, the bleeding was stopped at once. In the purulent forms it was noticed that the pus was soon suspended. The pain given was rather sharp at first, but soon became tolerable, and in very many cases there was no pain felt at all. There was no fever, and in twenty-four to thirty-six hours afterwards a loss of rose-colored serosity was seen, which preceded the rejection of the scab, that was usually found in the linen, in five to nine days afterwards. In one hundred cases this method gave ninety-six cures without any complications. In the other four perimetritis set in, because the women got up the day after the cauterization, but even these cases were cured afterwards. After the fall of the scab, the vagina was again washed with a solution of corrosive sublimate, and on passing the catheter the cavity of the uterus was not found in a contracted state. The menses returned in all cases, and in two cases pregnancy followed the treatment.

Lactose as a Diuretic.—Dr. Germain Sée publishes his experiments in undertaking to find out what it is

in milk that causes the diuretic effect, and he finds that it is not water, caseine, albumin, fatty substances, or salts contained in the milk, but simply the lactose or sugar of milk that gives milk its diuretic power. One hundred grammes of lactose dissolved in two quarts of water (which may be flavored to taste), and given in twenty-four hours, is his prescription, and it makes patients urinate two and a half quarts of urine the first day, and three and a half the second, and four quarts the third day, when it becomes stationary or else falls to two and a half quarts again, slowly. The sugar of milk presents this advantage over milk as a diuretic that it does not determine glycosuria or azoturia, while milk, if given in four-quart ration per day, may do so. The new diuretic acts well in hydropsias of heart origin, but fails in those of renal; when there is any lesion of the kidney it will not act well. It is probable, then, that lactose is a diuretic by its action on the heart. The great advantage of this new diuretic is that it can be used in those heart cases that cannot support milk.

Treatment of Phthisis.— Dujardin-Beaumetz, in a late clinic on this subject, regrets that we have not yet advanced much in the way of treatment of this disease. The many preparations that of late have been used by hypodermic injection with vaseline oil as a base, do not seem to bring about any modification in the pulmonary tract. Iodoform is still used; 1 gramme of it will dissolve readily in one hundred grammes of vaseline oil, and a syringe full is injected every day into the shoulder. Roussel, of Geneva, advises eucalyptol, in equal parts with vaseline oil, used in the same way. Some of the patients get a better appetite, spit less, and get stronger, but the lesions remain the same. Creasote is much the fashion, and as much as four grammes a day of it have been given, but the results are not brilliant. Gimbert, of Cannes, injects as much as ten grammes under the skin, and says that he cures some patients, but it will be found that creasote upsets most stomachs. The various gases (hydro-fluoric and others) produce a certain diminution in the expectoration, but do not cure. Hot air is being tried, but the results are uncertain, so that M. Dujardin-Beaumetz is forced to tell us that we must fall back on *sur-alimentation* and hygiene. Do not trouble these patients' stomach, at the same time try to feed them up; give them milk, fatty substances, as much as you can, such as oil, goose-grease, butter, cream, soups with flour and grains; but while recommending a little good wine, do not allow the stomach to become enfeebled by alcohol. After alimentation in importance comes climate. Oxygenation is the great point, and as much open air as possible, no matter where it is; but best where the temperature is not over 12° to 15° (Fahrenheit 60°) in winter. In a word, we have to confess that we are reduced to alimentation and respiration of pure air in this disease.

Treatment of Warts.—A bright young physician, formerly in Paris, now in Gibraltar, Dr. Imossi, gives the following new treatment for these troubles: He gave simply ten drops of tincture of iodine in a half glass of water twice a day. In ten cases, some of whom had warts all over the face and hands, a complete success was obtained. It is curious to note that iodine given in this way brought about a loss of weight, that ceased, however, when the medicine was no longer given. From this indication, Dr. Imossi used it in some cases of obesity, and in those who wished to train down to ride horses in a race. As much as ten pounds weight was lost in two weeks' time. Iodide of potassium has also been used in obesity, but the iodine tincture seems to be superior in its effects. In regard to the disappearance of warts under the influence of tinct. iodine, internally, the explanation given by Dr. Imossi is that iodine has an influence similar to that seen when used to disperse scrofulous swellings.

Ought We Take Prophylactic Precautions in Pneumonia in Regard to Contagion?—Dr. Cruigneau asks this question owing to having seen some cases of pneumonia in the same family, one after the other. First, a lady had a severe case, and notwithstanding due care and treatment she died at the end of eight days, and a few days afterwards her brother-in-law was down with pneumonia in the same house, and died also in eight days. Is this an example of contagion or accident? The members of the medical society to whom these questions were put thought that it depended on what kind of pneumonia we have whether we insist on isolation or not. All classes of pneumonia were not contagious. Dr. Chantemesse found that the saliva of a patient with pneumonia injected into guinea pigs gave them constantly the disease, and there is without question a microbe, whether it be that of Fränkel or Friedlander, but besides this there is the question of culture ground. Some people are more liable to take pneumonia than others. Perhaps it would be wise to isolate all the aged members of a family where there is pneumonia, and, above all, those who may be addicted to alcohol. Certainly, all expectoration should be burnt or disinfected in some other manner. In any case, as pneumonia is certainly infectious for many persons, it would be a wise plan to isolate as much as possible.

The action of liquids obtained by trituration of the glands of animals has been studied by Professor Brown-Séquard. He takes the testicles of guinea pigs and rabbits, in the fresh state, and obtains the contained liquids by trituration, which he injects under the skin, after adding a small quantity of distilled water. M. Brown-Séquard did not hesitate to try the method in his own case, and he says: "Those who knew me six months ago saw that I was an old man (seventy-two), that I was weak and failing in health, that like most old people I found that the bladder and rectum no longer acted as they should do. Since I have taken to hypodermatic injections of testicular fluids I am twenty years younger in feeling, the bladder and rectum act normally, and I work now twelve hours a day without trouble." Dr. Brown-Séquard's success has not failed to induce others to try his new method of treatment for old people who suffer from the weakness due to old age. Dr. Variot has just made a communication to the Sociéte de Biologie in which he gives details of three cases of weakness due to old age, treated by subcutaneous injections of a liquid extracted from the testicles of

guinea pigs and rabbits, and the success was as great as in the case of M. Brown-Séquard himself. The high position of this last professor in physiological science demands that any suggestion that he makes be treated with due consideration, no matter how extraordinary it may seem at first sight. It will not be long before we shall be able to confirm or deny the efficacy of the method.

Dr. Brown-Séquard also injected the liquids obtained from the other glands of the body, and he finds that that obtained from the lungs is toxic, that from the liver and kidney is indifferent, and that from the testicle salutary. He thinks also that the liquid obtained from the ovaries may be tried in weakness from old age in women, and is now making experiments to prove this point, and asks some of the lady physicians to try it on themselves.

On Chronic Arsenical Poisoning.—Prof. Brouardel, who holds the chair of legal medicine at the faculty, where he is the dean, has been able to study this subject owing to some wholesale poisoning by arsenic at Hyéres, a short time ago, where it was found in large quantities in wines sold by a druggist. The symptoms in chronic arsenical poisoning are not well known, and Dr. Brouardel has now shown them to have four periods. First, digestive troubles; second, eruption and a catarrh of the larynx and bronchial tubes. The third period is one of troubles of sensibility; and fourth is paralysis. We have not space enough to give the symptoms in detail, but simply state that they always pass in the above order. Dr. Brouardel gives a good method of proceeding, if we are desirous of finding out if arsenic is being used, that is to ask for a sample of urine of the person, and have it examined for arsenic. This can be done without arising the suspicion of any one who may be using arsenic with criminal intention on a patient. The hair also, of a person taking arsenic for a long time, will give the proper indication, and even the bones after death will tell the effects of chronic arsenical poisoning. THOMAS LINN, M.D.

PARIS, July 3, 1889.

THE CURE OF BACILLARY PHTHISIS.—Dr. Lahusen, of Hanover, reports the following case of pulmonary tuberculosis, treated according to Krull's method (the inhalation of warm, moist air), resulting in a cure:

Oscar Schwaneke, engineer, aged thirty-two years, presenting no hereditary tendency to lung disease, had been ailing during the past ten years, in spite of which he continued for seven years building railroads in North America. About July 1, 1887, he took sick with severe palpitation of the heart and lancinating pain in the left side (pleuritis?). On July 9, he traveled to New York, thence to Europe, and arrived at Hanover July 22. Cough, difficulty of breathing, and increasing general weakness were now developed, and the patient took to bed. Hæmoptysis, diarrhœa, night sweats, now supervened; in fact, all the symptoms grew alarmingly worse from week to week, so that his physicians did not hesitate to inform his relatives that his condition was absolutely hopeless.

In this state I undertook the patient's case. Reduced to a skeleton, he suffered from anorexia, insomnia, colliquative diarrhœa, and sweating. His face was slightly cyanotic, his sputa scanty, bloody, purulent, and containing numerous tubercle bacilli, partly aggregated in masses. These symptoms, corroborated by all the physical signs, left no possible doubt as to diagnosis, nor, of course, as to a correspondingly hopeless prognosis. In short, he presented the pronounced picture of a *moribundus* who could not live fourteen days longer.

Through a mere accident I had become informed of the results of Dr. Krull's experiments, not then yet published, and I ventured, with the help of three men, to transport the dying patient to Güstrow, Dr. Krull's residence, where he arrived more dead than alive. The first news thence was a storm of reproaches, well deserved, as I thought, because even Dr. Krull himself was unwilling to attempt the curative treatment of the dying man. However, upon the relatives prayers and my own persuasions the treatment was begun.

This is not the place to republish Krull's method, but I may state that at first the inhalations were made at 43°–44° C. (109.40°–111.20° F.), for thirty-five minutes, later on at 41° C., and still later at 40°, while the duration of the sittings was gradually shortened to fifteen minutes. I will skip the period from September, 1888, to January, 1889, during which period the reports, at first from Dr. Krull, then from the relatives, and finally from the patient himself, arrived in the beginning hopefully, and later on more and more favorably, until my expectations were raised to the highest point. When, about January 1, Mr. Schwaneke stood before me, these expectations were more than realized. I saw before me a gentleman normally nourished, whose weight had increased from 123 to 140 pounds, whose appetite, sleep, and digestion were normal, and whose pain, cough, and asthma had vanished.

An examination of the lungs showed an almost complete absence of objective symptoms; here and there a few coarse râles or indefinite breathing sounds. Percussion sounds everywhere normal. The sputum consists almost altogether of mucus and saliva, and contains not a trace of tubercle bacilli.

It must be stated here that the winter season was very rough and variable, and that there is no perceptible climatic difference between Hanover, the province of the patient, and Güstrow, the home of Dr. Krull.

Dr. Krull's treatment was not modified upon the patient's return. He continued with a daily inhalation from his apparatus at 40°, and diligently practised a toxic, strengthening regimen. The sounds upon percussion and auscultation are now normal over the whole extent of both lungs, except an area the size of a mark at the anterior border of the left axilla, where are noticed the evidences of cicatricial contraction. His general well-being is perfect. He subjects himself to no restrictions whatever, and intends shortly to return to the United States and resume his business. He now weighs 151 pounds, heavier than ever before in his life.

PUBLIC DUTIES.

IN one respect, England stands at the head of the world; and that is in the attention she pays to public hygiene. This is probably a late consequence of the Norman conquest, which placed the finest race of fighting men the world has ever developed in authority over the most stubborn nation in existence. The Norman long ruled England by the strong hand, and to-day he does so by demonstrating his inherent fitness to rule. For though the strain is diluted and divided into many channels, it is yet the same powerful race which still holds the reins of power; the Norman still forms the steel head to the Saxon spear.

To this fact England owes her admirable discipline; that power of combination which unites many persons for the pursuance of a common object; that sense of responsibility which leads her to look upon the consideration of general needs as a public duty. Who suppressed the slave trade but England? Who put down piracy on the high seas but the same trusty world's police? In our security from foreign invasion we Americans have in truth grown to be more insular than our progenitors. The time is coming, however, when we will be compelled to abandon this selfish policy, and take upon us our share of the responsibility of the world's doings; that share which our growing strength imposes upon us as a duty.

And there is no better way to prepare for these coming cares than to begin practising them at home. In our public duties, even to our own selves, we are wofully deficient. We spend our money freely to build up and beautify and render hygienic our own homes, but there we stop. A little patch of smooth paving will be put down in front of our house, but no further. Our neighbor's home on the back street may afford a lodging for any pestilential disease, and the streets of the city may be wretchedly paved, impossible to clean or keep in repair, but we make no effort to remedy the evil. That is, no combined effort, no movement as a community, such as would result in an abatement of the nuisance. Here is where the lack of discipline, of public spirit, is shown.

Take, for instance, the report of the Medical Inspector who has been examining the sanitary condition of the Philadelphia public schools. We are ashamed to print the disgraceful list of foul cellars, leaky wells, etc., polluting the air which our children are compelled by law to breathe. Compulsory education is a good thing; but the community which compels the parent to send his child to school incurs thereby obligation to provide suitable school accommodations; and the word suitable surely includes sanatory.

But our wealthy citizens spend their money freely to render their own homes safe, and our political leaders arrange their slates and lay plans to secure control of the offices; our physicians pocket their fees for attending diseases engendered by filth; our clergy assiduously war on the enemy of souls; our journals regulate the affairs of the nation, especially the pugilistic and base-ball interests, and all agree in neglecting the duty which lies nearest their hand. So, when the heated season comes, each one flits off from the city, carrying his little ones to the healthy seaside or mountain resort, and leaving their brethren to struggle with the noxæ of the city. One hundred and twenty-eight deaths in Philadelphia, last week, from cholera infantum! eighty-three from contagious diseases, every one of them preventable! For every one of these deaths the public — that is, every citizen of Philadelphia, individually — is morally responsible. For every case of sickness contracted by a child in the public schools the city is legally responsible. There is no reason why Philadelphia, in mid-summer, should not be as salubrious as Newport. But each one says to himself: "I alone am powerless;" and so nobody does anything; and the evil goes on, and the innocents are slain, because we have not as yet become sufficiently civilized to unite ourselves for the accomplishment of a common object; because having secured ourselves, we tightly clasp our purses and refuse to open them for our neighbor. When men's minds are deeply stirred by great calamities, the contributions come quickly enough; but for that higher philanthropy, which comes not from impulse, but from the settled conviction of duty, which rules the lives and governs the actions of men continuously, we do not possess it.

This absenteeism is more heartless than that of the Irish landlord. Every member of the classes mentioned above should be compelled to stay with his family in the city through the sickly season, until his own danger rouses him to a sense of his duty to the public. For if the politicians, the clergy, the medical profession, the newspapers, and the men of wealth, were to unite in the demand that the city be put into

a proper sanitary condition and kept there, who can doubt but that it would be done? But it's easier to blame it on the Schuylkill.

IN the death of Dr. Ellwood Wilson, Philadelphia loses one who has been for many years her leading obstetrician. Dr. Wilson's success was not due to any adventitious aids, but to his own exertions; as he came to the city a poor man, without influential friends. He leaves two sons who have already distinguished themselves among Philadelphia physicians.

Annotations.

THE QUININE HABIT.

WE have the alcohol habit, the opium habit, several other minor "habits," and now there bids fair to arise a new one—the quinine habit.

Opium, alcohol, arsenic, and the like, are most valuable weapons in the hands of the skilled, but they are two-edged, and, therefore, should be used only by the expert. The same may be said of quinine; but since the duty has been taken off this drug it has become so cheap that it is now found on every household shelf, along with the arnica bottle and the patent medicine for colic.

Many are learning to depend on quinine for stimulation just as others do on alcohol or opium, and the result will be little better. A corrspondent in the *Medical Brief* says that he knows of a man who depends so much on quinine for support that, becoming unnerved in a railway station, he was compelled to take a large dose of the drug and sit quiet till it took effect.

The attention of medical men generally should be called to this growing evil, so that they may use their influence against it.

Quinine is not so harmless that every baby may have a bottle of the drug in its carriage, but is one the indiscriminate use of which may result in much ill.

A NEW VIEW OF A CERTAIN FORM OF SUBSTITUTION.

THE preparation known as Febriline has been shown to consist of quinidine, instead of quinine as claimed by the manufacturers, who, on their part, have been held up to the world as objects of scorn for the deception. A very pretty fight, as Sir Lucius O'Trigger would say, might be made upon the question of whether there is anything to find fault with in their action. On the one hand, it is assuredly wrong to sell one thing under the name of another. Even when an enterprising Philadelphia house sells "bovine" vaccine points which cannot be distinguished from the "humanized" variety in the certainty and mildness of their action, a wrong is done; because, though the purchaser gets a better article than he asks for, the bovine virus gets a credit it does not deserve, and of which it robs its competitor.

On the other hand, it may be said that quinidine costs as much and is worth as much, grain for grain, as quinine; that it has certain advantages over the more popular salt, in that it has less taste and can be given to children more readily; it is less irritating to the stomach, and does not cause such cerebral distress; while for some purposes, such as its use as a prophylactic by persons going to a malarial district, it is superior in efficacy. Competent authorities in India recommend a daily dose of three grains as sufficient to keep off the attacks of malaria. We have utilized this hint in a number of cases, in which it proved successful in preventing malaria when patients were compelled to resort to malarious places. The only reason quinidine is not used more is the fact that as yet we are not very scientific; at least we are not scientific enough to be sure of our science, and neither physician nor patient can forego the moral effect of using a tried and trusted remedy. Even should quinidine be equal in dynamic activity, it would be given and taken with a grain of doubt, which would lessen its action. But call it quinine and this objection is lost. Now, if it be pardonable to mystify a patient a little by a bit of clap-trap, and no physician can succeed who fails to array the mental forces of his patient on his side, is it not equally justifiable for the druggist to do the same to the physician, if the conditions are alike?

SUIT FOR MALPRACTICE.

A SUIT for malpractice was recently instituted against a physician in Ireland, on the ground that he dismissed an obstetrical case as well, whereas there was an inversion of the uterus. Three weeks after his departure, another practitioner was called in, who testified to an inversion.

But as the patient had not obeyed her first physician's directions with regard to rest, and as several medical men testified that the inversion might easily have occurred after he left the case, the judge properly dismissed the suit. If many more of such suits, which are often entered into through simple vindictiveness, had so summary a termination, it would serve materially to lessen the number recorded.

KNOW YOUR MILKMAN.

HUMAN nature is weak, and the milkman's, especially, is often weaker than his milk. Probably his moral strength is not more frail than that of other venders and manufacturers of different commodities, who adulterate their products without the slightest compunctions of a guilty conscience; but, unfortunately, there is more to be dreaded from improper milk than from any other eatable or drinkable substance, since it forms the chief and often the whole food of infants, and is also an important article of the diet of older persons.

In cities is where danger is mostly to be feared, especially as the hot season is now upon us; and we write to warn physicians and others that there is only one certain way to secure pure milk, viz., to secure a reliable milkman. We acknowledge that this is a difficult task, but it is the only method by which the consumer can feel assured of what he is getting.

Bottled milk looks well, and the name sounds well, but unless you are certain of your milkman's code of ethics, the bottles may have been filled directly from

the can, and that too, without having been washed.

As to the little sign "Farm Dairy," suspended here and there over milk shops, it is merely a delusion; and if the buyer supposes that the milk there sold smells of the clover-scented farm fields whence it was straightway exported, he is very sadly mistaken—excepting he knows his man.

Nor may high prices be relied on as a criterion of the character of the milk. There are grades of milkmen, as well as of the rest of mankind, and the consciences of some demand more money for keeping quiet than do those of others.

We know of a wealthy family in Philadelphia who paid a high price for milk, thinking thus to ensure a good quality; but one day, some doubt having arisen, a lactometer was bought, whereupon the milk was discovered to be far below the required strength. The milkman was informed of this experiment, and, singularly enough, the next day the lactometer registered two or three degrees above what science and the law required.

WE have been frequently requested to explain the references to the Almshouse controversy, which appeared in the *Medical and Surgical Rrporter* some weeks ago. The account in question was simply a tissue of misrepresentations. While it is not likely that Dr. Waugh would have been elected by a body composed almost entirely of men who are in affiliation and sympathy with the rival colleges, yet it is well known that Dr. Waugh's popularity and that of the Medico-Chirurgical College were not considered in the matter. Dr. White's letter made Dr. Waugh's election impossible; and members stated openly at the meeting, and have told Dr. Waugh since, that they came there prepared to vote for him, but could not do so after hearing this letter. These facts were perfectly well known to Dr. Dulles at the time he wrote his mendacious editorial; and by doing so he only showed to what lengths he was willing to go to help his side in the controversy, and gratify his jealousy of a successful rival. The only thing he has gained by his conduct, however, is the contempt of every fair-minded man.

IN looking over the report of Medical Inspector Taylor, on the public schools of Philadelphia, we are impressed with the ease with which most of the nuisances could be abated. Every school child knows that sewage will decompose, giving rise to gases which will rise from the receptacles and, laden with the germs of disease, diffuse through the air of the residences above them. Were it possible to smother these effluviæ, our plumbers with their clumsy traps would have done so long since. How thoroughly the object could be attained by giving the necessary and inevitable outlet to the gases, in a manner which will render them innocuous. Ventilation of privies and of sewers is neither difficult nor specially expensive. In residences a pipe running to the chimney is sufficient, and the heat produces an extracting current without extra cost. In the streets, every gas lamp could be made to contribute to the same object.

Letters to the Editor.

RETENTION OF URINE.

A RECENT experience has suggested to me a method of relieving retention of urine when due to spasm, that I have never seen described in any text-book or monograph, although, like the Allen surgical pump, it is so simple that I wonder the method has not been previously employed.

Two months ago I had a patient with retention of urine of several hours' duration. An attempt at catheterization revealed the presence of a number of strictures, the deeper one of very small caliber; there was also a hard swelling in the perineum, wholly diverting the channel of the urethra. Supra-pubic puncture with a trocar relieved the bladder temporarily; then the perineal abscess was opened and drained, the urine passing off through the drainage-tube. The anterior portion of the urethra was dilated slightly, and urine passed slowly through it as the abscess healed. After the extensive infiltration of the surrounding tissues was absorbed, gradual dilatation was resorted to. One Saturday evening I passed a No. 12 French bougie, but was unable to pass the site of the abscess. Sunday afternoon the patient returned, complaining that he had not urinated since the previous evening. The smallest catheter brought up short against an obstruction at the depth of the abscess opening. Removing the catheter, I took the largest bougie which would pass the first stricture and introduced it till it was firmly grasped by the stricture; then directing the patient to strain gently, I slowly withdrew the bougie, and a larger stream of water flowed than for months.

I presume the action was a reflex one, akin to, although not identical with, the plan of turning on a stream from a hydrant, when the sound of the running water often overcomes spasm. The bougie slowly passing the stricture and rubbing it, gives a sensation similar to the passage of urine and presto! the urine falls into line and exits from the meatus.

Where there is simple spasm of the muscles of the neck of the bladder, as well as in the case of spasm accompanying organic stricture, this method can be employed, introducing the largest bougie that will pass the meatus, and withdrawing it while the patient endeavors to urinate. This method is decidedly preferable to catheterization, even when there is no stricture to make the introduction of a catheter difficult, for the bladder is emptied without any possibility of the introduction of germs therein.

I would like to know if others succeed as well with this plan, or whether, like many another scheme, it is successful only in the hands of the inventor.

An eminent lecturer on genito-urinary disease begins his lecture on retention with the words, "Gentlemen, what is all the world to a man when he can't urinate?" Truly, it is nothing, and if, indeed, I have discovered something new, I shall modestly rest content, as having introduced Bidwell's method for the relief of retention.

W. D. BIDWELL, M.D.

LEAVENWORTH, KAN.

CONCUSSION.

THE well-known destructive effect of violent concussion, or prolonged vibratory sounds on the lower forms of life, leads to the surmise that such agency might have a curative influence over diseases dependent on microbes. Some popular fancies and savage customs are based on reason, if the surmise be correct. The beating of tom-toms and the use of other rude musical instruments to exercise the evil spirit, would have its good effect in killing the bacteria causative of the disease. If the common belief in the purifying effect of a thunderstorm is well founded, we should attribute the beneficent action to the widely diffused destructive effect of the thunder on noxious miasms floating in the air.

The lightning has the credit in the popular mind, but the influence of the electrical current, confined as it is to the narrow space covered in its circuit, must be actually very small.

Again, I have seen it somewhere stated that epidemics have been modified by the continued firing of heavy cannon. All this would seem to justify the hope that sound might be made a factor in medicine. Laboratory experiment could easily determine whether explosive or prolonged musical sounds could destroy the vitality of the various disease producing bacteria.

In the higher forms of life different animals have been found to be deleteriously affected by different tones. The same may be true of microbes; a sound that would destroy one species might be harmless to another. A practical point is whether the sound vibrations can be transmitted to the tissues of the body, so as to destroy bacteria actually at their work of death. I have noticed that certain buzzing sounds give the chest a peculiar, somewhat disagreeable sensation of diffused internal jar.

Again, certain deep-toned musical notes would similarly affect the abdomen. The difference in sound required is due, I imagine, to the difference in density and structure of the tissues involved. This is merely a suggestion, but any suggestion at all plausible should merit the attention of those who are in a position to investigate and determine its value. The question is, unable to reach our microscopical enemies in any other way, whether we may not be able to shake the life out of some of them.

CHAS. TARVER, M.D.

SANTA ROSALIA, MEXICO.

ANOMALOUS CASES IN PRACTICE.

TRIPLET BIRTHS.

WAS called to see Mrs. B., wife of a farmer, in her seventh confinement. On arrival I found her in the second stage of labor, the bag of waters well distended, yielding in a few minutes, the vertex of a fœtus presenting, and, after a few pains, a female child was born. After applying a couple of ligatures, as is always my custom, and dividing the cord, I placed my hand on the abdomen in order to ascertain the condition of the womb, and discovered another fœtus, and upon examination, per vaginam, I found just within the vulva a foot presenting, but on pressing my index finger a little further I found another foot corresponding with the first, but no bag of waters. I disengaged the second foot, and in a few minutes delivered the patient of another well-developed girl. On making a third examination I found a second amniotic bag of waters, full and well distended, containing a third fœtus, the vertex presenting which was soon delivered, and proved to be a boy somewhat smaller than either of the girls. The placentas were consolidated into one mass. The first two fœtuses appeared to be surrounded by the same chorion and amnion, but the third had its amnion and chorion distinct from the others. The third stage of labor was very short as well as the others. The mother made as good and quick recovery as in any of her former confinements, and has not been pregnant since. The two girls are still living and in good health, but the boy died from cholera infantum the summer following his birth, when six or seven months old.

FRACTURE OF THE FEMUR.

Was called to see a boy ten years old, who had been thrown from a load of hay, producing a transverse fracture of the lower portion of the upper third of the femur. When I arrived I found him suffering with considerable pain and quite nervous, and had fears about keeping the fractured extremities of the bones in apposition, so I administered a dose of morphine, and in a few minutes applied a straight splint for a primary dressing, which remained on for a few days, when I changed it to a plaster-of-Paris dressing; the limb, being well shaven and moistened with sweet oil, was enveloped in a sheet of woolen cloth, the irregularities being filled up and protected by cotton batting, then applying short bandages, first dipping them in a solution of the plaster of Paris and applying quickly; used them short for convenience; applied one after another until they were several layers in thickness. By the time I got through and was ready to start home the dressing was so well set that he could turn himself in bed without injury. I visited him twice during the next two weeks, and heard from him often. On my last visit I told the family that I would call in three or four weeks from the time he received the injury, and remove the dressing. I returned on the twenty-fifth day and found the boy out in the yard on crutches; he said he got tired of waiting for me, and a few days before took his pocket knife and cut the dressing off. On examination I found the provisional callus well ossified. I have frequently seen him both walking and running since, but could detect no shortening.

F. G. STEPHENS, M.D.

SIDNEY, IA.

DR. R. v. BARACZ reports in *Wiener med. Presse*, January, 1889, two cases of actinomycosis, transmitted in the one case by kissing. Patients were bridegroom and bride. The bridegroom was first infected, and six months later the bride. The disease developed in both cases on the lower maxilla, near the seat of a carious tooth.

Book Reviews.

THE ESSENTIALS OF PHYSICAL DIAGNOSIS OF THE CHEST AND ABDOMEN. By J. WALLACE ANDERSON, M.D., of Glasgow. New York: MacMillan & Co. Pp. 156. Price, 75 cents. 1889.

This is a little aid to the student that we have no hesitation in recommending. Dr. Anderson has written in a style as compact as possible, with a view to economy of time, yet has satisfactorily covered his subject. The book itself is commendable in form, printed with good type, and of a generally pleasing appearance.

SYNOPSIS OF HUMAN ANATOMY. By JAMES K. YOUNG, M.D. Philadelphia and London: F. A. Davis, Publisher. Pp. 393. Price, $1.40, net. 1889.

This is another addition to the Physicians' and Students' Ready Reference Series," one of the multitude of such works that has arisen in late years. It is arranged in a methodical form, so that any desired subject can be readily referred to. The attempt at illustration, however, is rather a failure, this doubtless being mainly due to the fact that the cuts had to be made so small. Anatomical illustrations brought down below a certain size, unless the greatest care is observed, are liable to look like almost anything else but what they are intended to represent.

STRATHPEFFER SPA; ITS CLIMATE AND WATERS. By FORTESQUE FOX, M.D. London: H. K. Lewis, 136 Gower Street, W. C. Pp. 165.

Strathpeffer is situated in the Scottish Highlands, and, according to Dr. Fox, who has studied the subject thoroughly, is beautiful to the eye, restful to the body, and has both climate and waters suitable to many classes of invalids. Dr. Fox makes a suggestion that might well, with changed places, be heeded by some of our own physicians, namely, that they have as good waters and health resorts in the United States as there are on the Continent. The book is neatly printed, attractive looking, and embellished with several illustrations.

LECTURES ON MASSAGE AND ELECTRICITY IN THE TREATMENT OF DISEASE. By THOMAS STRETCH DOWSE, M.D. Bristol: John Wright & Co. London: Hamilton, Adams & Co., Paternoster Row. Pp. 379.

Books on these two subjects are now becoming quite plentiful, and, as would be expected, we find the same variance of opinion that exists among teachers of other branches of the healing art. The very fact that so many works have arisen on massage and electricity shows how common treatment by such means is coming to be. Hippocrates has, as usual, been referred to as acquainted with massage, though it is only within late years that the medical profession has made much use of it; and already, some with that very human tendency for extremes, are recommending massage for anything and everything. In a few years it will doubtless fall into its proper place as a valuable therapeutic agent for the physician's armamentarium, but not a specific for all diseases mental, moral, and physical.

Dr. Dowse discusses the subject of massage quite thoroughly, but does not give much space to electricity, treating it rather as complementary to the other.

Gleanings.

BALLARD (*Lancet*) claims that the microörganism of summer diarrhœa is capable of manufacturing from food a virulent chemical poison, which gives rise to the symptoms.

AUSTRALIAN WINE.—Australian wine is rapidly rising to the level of that of France and Germany, and the London *Lancet* predicts that it will soon come into general use.

PHELPS (*Med. Record*) advances the idea that the diminution of free hydrochloric acid in cancer of the stomach is due to the neutralization of the acid by the ptomaines produced by the cancer organisms.

There is a good deal of, as yet unproved, assumption in this theory.

KLEIN has pointed out very forcibly the danger resulting from the use of meat and milk from tuberculous cattle. While the transmission of pleuropneumonia, cattle plague, puerperal septicæmia, etc., has not yet been demonstrated, the meat of animals dying of these diseases should not be sold, as it has not been shown to be harmless. He adverts to the salutary regulations of the Mosaic code on this subject, and says that tuberculosis is clearly described therein as rendering the animal unfit for food.

THE AFRICAN KOLA NUT.—There has long been a desire to obtain some food which, though comparatively small in bulk, would be of such extraordinary supporting character that soldiers and others, who have before them a day or more of extra exertion, could perform their work with greater ease and with less expense to their physical strength than at present.

When coca erythroxylon was first introduced, attractive tales were related of the wonderful revivifying and staying properties of the coca leaves, and they were accordingly put up in all sorts of masticatory forms; but although there is little doubt that the South American natives are strengthened by chewing coca leaves, that quality seems to be lost on the trip across the sea, for it is not found in the imported leaves. A new food is now introduced—that made from the African kola tree. Dr. Heckel, of France, is the pioneer. He succeeded in getting the French government to try the food on soldiers and horses engaged in exceptionally arduous work, and with most gratifying results. It is said that the taste of the kola nut is slightly bitter, but that after eating it, water, no matter how bad, becomes palatable. If this be true, such a quality will not be numbered among the least of its virtues.

NASAL CATARRH.—After briefly reviewing the various methods of treating catarrh and pointing out the reasons for their failure, Beverly Robinson (*N. Y. Med. Journ.*) recommends the nebulization of oil containing carbolic acid, as carrying the agent to every part of the affected membrane and retaining it there.

NITRO-GLYCERIN VS. ALCOHOL.—Burroughs (London *Lancet*) lauds nitro-glycerin as a quick stimulant in place of alcohol. In its favor are; small bulk (one drop of a 1 per cent. solution is the ordinary dose), rapidity of action, the fact that it can be given to an unconscious patient by simply putting a drop on his tongue.

NEUFIELD, a Polish physician, has recently mentioned several cases of injury in which there was a subcutaneous escape of lymph. A fluctuating swelling was noticed each time over the seat of the blow. The best treatment, he thinks, is to evacuate the contents at once. He has never met with any mention of subcutaneous lymphorrhagia in the text-books.

SUMMER DIARRHŒA.—CARHARTT (*K. C. Med. Index*) recommends the stoppage of milk as a diet, and the substitution of liquid peptonoids with coca, pure brandy, and beef tea or broths. Water must be allowed freely, given in small quantities and often. In bad cases he gives:

℞.—Acidi salicylici . . . . . gr. xxx.
Cretæ precip. . . . . gr. x.
Glycerin . . . . . ʒij.
Aquæ rosæ . . . . . ʒxiv.—M.
Sig.—Fluidounce every hour for a child one year old.

LOOMIS' DIARRHŒA MIXTURE.

Take of tincture of opium . . . . . ½ fl. oz.
Tincture of rhubarb . . . . . ½ fl. oz.
Compound tincture of catechu (U. S. P.) . . . . . 1 fl. oz.
Oil of sassafras . . . . . 20 mins.
Compound tincture of lavender, enough to make . . . . . 4 fl. ozs.

SQUIBB'S DIARRHŒA MIXTURE.

Take of tincture of opium . . . . . 1 fl. oz.
Tincture of capsicum . . . . . 1 fl. oz.
Spirit of camphor . . . . . 1 fl. oz.
Purified chloroform . . . . . 180 mins.
Alcohol, enough to make . . . . . 5 fl. ozs.

THIELEMANN'S DIARRHŒA MIXTURE.

Take of wine of opium . . . . . 1 fl. oz.
Tincture of valerian . . . . . 1½ fl. ozs.
Ether . . . . . ½ fl. oz.
Oil of peppermint . . . . . 60 mins.
Fluid extract of ipecac . . . . . 15 mins.
Alcohol, enough to make . . . . 4 fl. ozs.

VELPEAU'S DIARRHŒA MIXTURE.

Take of tincture of opium,
Compound tincture of catechu (U. S. P.),
Spirit of camphor, each . . . equal volumes.—M.

HOYOS (*Revista de Ciencias Médicas*) reports an instance in which he probably saved a patient's life, by compressing the aorta with his hand in the uterus. The woman was almost *in extremis* from the post-partum hemorrhage, and the doctor having been called in hastily, whilst extracting clots from the uterus, felt the pulsating aorta and pressed his fingers against it, until he could have srought the necessary instruments and medicines.

POISONING FROM BUTTER.—If butter be not rancid it is generally considered to be safe eating, yet a case of supposed butter poisoning was lately reported in Chicago. It was butter that had been scraped from a jar packed in the country. If this report be true, the case affords an argument in favor of oleomargarine, for no instance of poisoning has yet been ascribed to it; and people in moderate circumstances must buy the packed butter as it is cheaper. The poison in this case was probably lead, dissolved from the jar by the agency of the fatty acids; as ptomaines, being nitrogenous bodies, cannot be derived from fats.

CHROMIC ACID FOR SWEATING FEET.—In compliance with an order of the Medical Department of the Prussian War Ministry the following was reported concerning the use of chromic acid in the treatment of sweating feet among the military:

1. According to the great majority of army physicians, chromic acid acts more promptly than any other remedy, and is of at least equal efficacy with the salicylic preparations. Its application immediately and considerably improves the marching capacity of the men suffering from the evil. It is unanimously reported that the fetor disappears very soon after the first application.

2. The remedy is cheap, clean, and easily applied.

3. It is to be regarded as harmless when applied in proper amount and strength. The weaker solution must be used first; and when this fails, but is well borne, then the stronger may be resorted to.

4. The applications must be made by the physician himself, or else by the assistant under his direct supervision.

5. Open sores on the feet must be healed before chromic acid is applied.

6. The proper mode of application appears to be the painting of the thoroughly washed and completely dried feet, by means of a camel's hair pencil, with a 5 to 10 per cent. solution in water of the acid, a short time before retiring. In many cases a single application is sufficient; in most cases, however, two to three treatments must be made to attain a cure or improvement. Should a repetition be necessary an interval of eight to fourteen days must be allowed to elapse, when the hardened epidermis will have been cast off.

Forty-two per cent. of those treated were cured, 50 per cent. improved, and 8 per cent. not cured. About 0.75 per cent. suffered from slight inconvenience, such as blistering, eczema, etc., caused chiefly by the use of the stronger solutions.

—*Deutsch. Militärärztl. Zeitschr.*, No. 5.

ELECTROLYSIS IN THE TREATMENT OF STRICTURE OF THE RECTUM

was the title of a paper read by Dr. Robert Newman, of New York, in the Surgical Section of the American Medical Association.

He reported twelve cases in detail, the first of which had been treated in 1871; all of which had occurred in his own practice. The *modus operandi* is virtually the same as in stricture of the urethra. A good galvanic battery is used, and the negative electrode is introduced per anum to the seat of the stricture, while the positive sponge electrode closes the circuit, and is placed in the hand of the patient, or on some other part of the body. The strength of current applied varies from five to fifteen or even twenty milliampères, according to the seat of stricture, the nature of the neoplasm, the size of the electrode, and other conditions. The *séance* may last from five to fifteen minutes, and under certain circumstances may be prolonged to thirty minutes. No force should be used, the electrode should be kept steadily against the stricture, and only guided until the electrolytic action does the work of enlarging the caliber, and then the instrument passes the obstruction. The electrodes have at one end a metal bulb of copper or brass, which is silver plated, some are flat, others round; the latter more egg-shaped; they are made in sets of different sizes. The stem of the electrode, except the extremities, is insulated with hard or soft rubber, some stiff; but most of them are flexible. Sometimes needles are used as the negative pole. *Séances* may be repeated in one or two weeks. The report of the first case is interesting and complete, and proves the perfect success of the treatment by a post-mortem specimen; the patient having died later of peritonitis. The microscopical examination of the specimen found no heterologous tissue, and nothing strictly neoplastic.

All the other cases are minutely reported, and documentary evidences added from different reliable sources.

In recapitulating the facts in these twelve cases, we find some interesting items. It seems that females are more subject to rectal strictures than males, as out of twelve cases only two were males. Their ages run mostly between thirty and forty, the youngest was twenty-four, the oldest sixty-two years of age. The two males were comparatively young men, respectively twenty-three and twenty-six years old. Eight cases were single, four were multiple strictures. The duration of the malady was from six months to twenty years, the causes varied, but hemorrhoids and constipation were important factors. Other causes were syphilis, venereals, enteritis, and dysentery. A rectal stricture, however, may follow any inflammation of the rectum. One case had the complication of five fistulæ, commencing in rectum and ending externally in different parts, in vulva and gluteal regions. As soon as the stricture was cured the fistulæ healed up without any treatment. Only two cases had no previous treatment, two had medical, and the balance surgical treatment; six of which had been operated upon with the knife; yet not in a single case had the previous treatment been successful; all were entire failures; and all that can be claimed in some exceptional instances was temporary relief, followed by relapses. Even the most sanguine operator will admit that proctotomy must be followed by the use of a rectal bougie at intervals. If we compare other methods with electrolysis, we find that the latter has at least improved every case, and in the majority of instances has effected a cure. The three cases, 5, 6, and 8, were certainly improved; but in the end may not prove satisfactory. One patient had too many complications, and could not have been permanently benefited. The second was an aggravated case, and the patient too poor to attend to herself, or even to come regularly for treatment. The case was then operated upon, and afterwards she had to use a rectal bougie regularly, by which means she kept the stricture from closing up again, but after four years had a relapse, with complications, and finally died. The improvements in the third case, No. 8, have been graciously acknowledged by several surgical celebrities; the patient, however, had to leave the city, thereby interrupting the treatment, and a papillomatous growth, which by some was considered cancerous, complicated the case to such a degree that a cure could scarcely be expected under any treatment. These cases are given just as they were, without claiming any success. The remaining nine cases, however, were cured by the electrolytic treatment; and as far as known no relapse has taken place, the time varying from one to ten years, excepting one case, from which nothing has been heard.

The best results were obtained from the method used in the treatment of urethral strictures by electrolysis—*i. e.*, by metal bulbs as negative, and weak currents at intervals; but from the nature of the parts treated, the current can be applied stronger and oftener than in the urethra. In the latter a current of five milliampères is considered strong, while we may in the rectum increase the current to fifteen and sometimes to twenty milliampères; prolong a *séance* from ten to thirty minutes and repeat it in four days.

Stronger currents and the treatment by needles have not proven as successful.

Dr. Newman hopes not to be called too sanguine or an enthusiast, when he makes the following conclusions:

1. Electrolysis in the treatment of stricture of the rectum is not a panacea, on the contrary, failures happen, in fact failures may be expected if the stricture is due to carcinoma.

2. Electrolysis will give improvement to the rectal stricture, when all other means have failed.

3. Electrolysis will cure a certain percentage of cases without a relapse, better than other modes of treatment, and without the necessity of using an after-treatment, or using bougies.

4. Fibrous inflammatory strictures are most amenable to treatment.

5. The best method of treatment is by a metallic bulb as negative, weak currents, and intervals of four days to two weeks. (Further experience, however, may change this rule.)

From other reliable sources more cases of successful treatment by electrolysis are added, as also extracts from letters, as follows:

1. One case of stricture of the rectum treated with electrolysis by Samuel Benton, M.D., M.R.C.S., of London, and in a private letter Dr. Benton writes: The two patients, whom I treated for stricture of the rectum by electrolysis, and published the cases, have remained well, and are permanently benefited.

2. Dr. W. T. Whitmore, of London, writes, that he has treated cases successfully with electrolysis. His paper was read at a meeting of the West London Medico-Chirurgical Society, and is not in press.

3. Dr. W. E. Stephenson, of London, writes: "Strictures of the rectum can, like all other strictures, be treated by electrolysis. The amount of success achieved by these means, depends upon the nature of the obstruction; in some cases a cure can be effected."

4. One successful case by Dr. S. T. Earle, Jr., of Baltimore, who has kindly sent the note. It was a case of syphilitic stricture of the rectum of long standing, treated successfully by electrolysis, no other remedy or medicine being used during the treatment. Previous operation by posterior linear proctotomy gave no permanent benefit. The result of electrolysis has exceeded his most sanguine expectations, and the patient has had no relapse.

PHENACETINE.—Dr. Mahnert found that phenacetine, in doses of gr. 13½, and in children, gr. 4½, given about two to three times daily acts nearly as a specific in acute articular rheumatism.

Large doses only once administered are preferable to small doses frequently repeated, and have, except hyperidrosis, no other bad after-effect, whether weak heart or cyanosis, though the temperature may fall to 95°.

As an anti-neuralgic he used it in the lancinating pain of tabes, and the neuralgic pain of the trifacial nerve with marked good results.

—*Deutsche Med. Wochenschrift*, 5, 1888.

BROWN-SÉQUARD ON THE HYPODERMIC INJECTION OF THE TESTICULAR LIQUID.—In a communication to the Sociéte de Biologie, Brown-Séquard offers the following notes as confirming the results already obtained:

If M. Brown-Séquard no longer possesses youth, as far as his age is concerned, he certainly has found it as regards vigor. He finds himself thirty or forty years younger, and all persons with whom he is brought in contact can testify to the marked change which has taken place in him since he commenced the injections of the testicular liquid. His power of resistance to fatigue is notably increased, so much so that he was recently enabled to make two voyages to Havre and to Boulogne without experiencing the slightest lassitude; he reaffirms that intellectual work has become much easier to him, and that the act of defecation no longer requires any assistance. But one injection has been made since June 1 (two weeks), notwithstanding which the vigor is still conserved.

It is not to an organic modification that we must attribute a change so rapid, but to a dynamic action of the testicular liquid. We know, besides, the influence of the spermatic secretion on the muscular and intellectual power, and all abuse of coition is sure to be followed by the loss of the forces and of the intelligence. M. Brown-Séquard states that persons who are abstemious in this regard for a certain length of time will find themselves more vigorous, and he quotes the example of a professor in London, who having to perform some difficult work, remained absent from his wife for about twenty days in total abstinence.

As early as in 1869, in the lectures given at the École de Médecine, M. Brown-Séquard studied the action of the glands for the purpose of determining whether they did not produce an internal secretion, and in this way bring on a modification of the blood. It would be well if the chemists would take up this study and inform us on the point. Uremia, which has given rise to so many theories, may be due to an action of this kind.

In terminating Brown-Séquard asked those who experiment to make researches in this new direction which he has outlined. It would be interesting to know what would take place in women, not only under the influence of injections of this liquid, but also after an injection of a liquid which could be obtained by compression of the ovaries. He also makes an appeal to the good will and devotion to science of the female practitioners of medicine. The above is that which has been accomplished and that which concerns us.—*La Tribune Médicale.*

ETHER IN HEART FAILURE.—Dr. M. Heitler saw in a patient over sixty years old, with atheroma of the bloodvessels and hypertrophy of the left ventricle, in whom suddenly insufficiency of the heart developed, with œdema of the lungs, and dyspnœa and cyanosis, all the dangerous symptoms disappear immediately after the injection of ether.

The seizures repeated themselves several times, and were every time marked off, with the ether injection, with the same prompt result. He noticed the same results of ether in weak heart in consequence of acute diseases, and recommends it for such cases very highly.

In heart failure, due to degeneration of the heart muscle, the result will only be transient; but if due to weakness only, or dilatation of the heart, it may save life.—Pester Pr., 5, 1888.

SEVERAL cases have lately been reported of "induced intoxication;" that is, a water drinker who passed the evening in company with a number of hilarious spirits, whose beverages were not represented by the formula H_2O, ended the sitting as drunk as his companions. Cut this out and show it to your wife next time.

Medical News and Miscellany.

THERE were 1187 deaths in New York last week.

THIRTY-EIGHT people suicided in Berlin during June.

GINSENG is gathered in the Catskills for export to China.

THE hot weather tells strongly on the city death record.

SEVENTEEN cases of diphtheria in Salem, Mass., since July 1.

A MAN in Danville, Ill., is said to have died lately of hydrophobia.

CHOLERA infantum prevails among Dover, Del., babies.—*Record.*

BLACK diphtheria is said to have broken out in a Minnesota town.

CHOLERA infantum caused 40 per cent. of the deaths in Brooklyn last week.

THE annual reports of ice cream poisonings are now beginning to come in.

THE Camden Board of Health is discussing the subject of a garbage crematory.

SIXTY cases of typhoid fever are reported in Wilkesbarre, and an epidemic is feared.

FOUL smells from a vacated canal bed at Huntingdon are blamed for the sickness there.

MORPHINE taking is said to be a dangerously common habit among Parisian ladies.

MANY ladies of Montreal are trying to have the McGill University opened to women.

THE best food for sick babies is the raw white of egg in cold water. Next comes raw beef.

DR. WILLIAM ELMER, of Bridgeton, died of Bright's disease, June 27, in his seventy-fifth year.

A BRIGADIER-GENERAL of the British Army stationed at Madras has been stricken down with leprosy.

SURGEON DUNCAN, who was supposed to have yellow fever, but really had remittent fever, has recovered.

DR. ALICE BENNETT has in view the establishment of a training school to fit nurses especially for handling the insane.

DR. RICHARD THOMAS, of Lancaster, died on July 14, of apoplexy. He was surgeon to a Jersey regiment during the war.

A CHINESE leper was discovered in the Sacramento jail recently. He had been sent there from Folsom for refusing to pay a poll tax.

THE French Government has commissioned Dr. Lowenthal, Professor at Lausanne, to go to Tonquin to test the efficacy of "salol" as a destroyer of the cholera microbe.—*Times.*

PARIS threatens to build three more Eiffel towers and erect a sanitarium on the four. This approaches our balloon idea.

CHARCOAL crackers may be readily prepared for dyspeptics by taking any ordinary crackers and burning them to a crisp.

A NEW method of wasting time has been instituted at the University of Pennsylvania, entitled the Department of Psycho-physics.

DR. S. WEIR MITCHELL will take his accustomed ocean voyage this summer, and while in England will visit Sir Morell McKenzie.

THE Italian Parliament is earnestly discussing the project of reclaiming the malarious districts about Rome, by means of cultivation.

DR. G. D. SCHOALES, of 1428 North Eleventh Street, was fined $25 by the Board of Health for failing to report a case of diphtheria.

DRS. JACOB HAY and W. S. Roland, of York, have been appointed to fill two vacancies in the United States Examining Board of that city.

THEY have only waked up to the necessity, in London, of having ambulances for wounded horses, and are starting a subscription for that purpose.

DR. CHAILLE states that the average life of woman is longer than that of man, and in most parts of the United States woman's expectation of life is greater.

A CASE of typhoid fever occurred in Harbor Creek, near Erie. On searching for the causes three decomposed toads and a lot of angle-worms were found in the well.

THE death of Francis S. Saltus, half brother of Edgar Saltus, is attributed to sulfonal. People who treat themselves have only a short time for experimentation.

DR. HENRY M. HURD, superintendent of the State Hospital for the Insane at Pontiac, Mich., has accepted the office of Superintendent of the new Johns Hopkins Hospital at Baltimore.

A WELL of impure water has caused typhoid fever in Parth Valley, and thirty persons have been afflicted within the past ten days, a physician among them. Three persons have died.—*Times.*

LESSENING the protection against disease is short-sighted economy. Owing to a failure on the part of Congress to make an adequate appropriation, the quarantine must be greatly cut down.

DR. PHILIP F. BRAKELY, the oldest practitioner in Northern New Jersey and a leading surgeon and physician, died at his home at Belvidere, of heart disease, aged seventy-four years.—*Times.*

"MEGALOCEPHALITIS" is the delicately euphemistic method by which the Philadelphia *Times* refers to what would in blunt English be dubbed "big-head fever." This affection, according to our classical contemporary, is especially prevalent among political office holders.

A TOUGH FIELD:—We heard the other day of a field that was so hard on the doctor that he had to give up his practice for three years, passing that period in a saw mill, in order to recuperate.

A NEWSBOY called at a doctor's office in Cincinnati, last week, and offered the medical man a half box of cigarettes "if he would make him feel better." He was suffering from scarlatina. Hence his rashness.

AN Alabama woman who had complained of stomach ache for eight years died, and in her stomach was found a piece of cloth thirteen feet long. So says the *Ledger*, but we would not care to vouch for the tale.

DR. MANLUFF, of Philadelphia, who is visiting in Dover, rode half a block at the latter place on a bicycle a day or so ago, to avoid the muddy streets, and for this he was arrested and fined $2.60.—*Record.*

THE Boston *Herald* in complimenting a young woman who graduated first in a class of forty aspirants in dentistry, suggests that the dentist's chair will lose some of its horrors when presided over by a fair female form.

DR. JOHN H. MUSSER, a graduate of the University of Pennsylvania, and for several years connected with the Philadelphia, University and Presbyterian Hospitals, has been elected Assistant Professor of Clinical Medicine at the University.

NEW YORK is going about the summer's work in the right way. She gets forty physicians to go and see the poor in the tenements, and pays the doctors, instead of letting them work for nothing and giving the credit to the societies.

Patrick Dunn, of Nevada, has a method still simpler than that of Brown-Sequard's for regaining youth. He has discovered a spring, and all that is necessary is to bathe a few times, drink the water, and presto, the ancient is a youth again.

A STORY is going the rounds to the effect that a two-year-old locked himself in to avoid a doctor, but the physician, equal to the emergency, put a ladder to the window, climbed in, and made the necessary application to the young strategist's throat.

HOW TO KEEP COOL.—Drink hot water, eat cold meat, avoid hot soups and ice water, take a hot bath twice a day, do your work in the early morning and evening, and from 11 A.M. to 4 P.M. keep in the darkest recesses of your house, clad only in pajamas.

ALMOST A FRANKENSTEIN.—A man with an artificial face has been attracting much attention at an English watering place. He has an artificial cheek, eye, and palate, fitted by a surgeon of Bristol. He eats without the slightest difficulty, and speaks distinctly.—*Times.*

APROPOS of the Bishop case the papers are raking up all the authentic and unauthentic cases of suspended animation ever heard of, with which to regale their readers. The fact is such that instances are exceeding rare, and it is a pity that the disproportionate fear people already have should be still farther excited.

PROF. HOWELL, of Johns Hopkins University, is quoted as saying that "many well substantiated cases are on record of the beard and hair growing long after the body had been interred." Surely this absurd popular error has not received sanction from such a man.

THE birth of a four-legged child in Indiana is plausibly explained by a daily paper on the theory of adaptability to environment. The Indianians have been doing little else than kicking since the 4th of March, and this occupation gives rise to a need for more legs.

DUKE CHARLES THEODORE, of Bavaria, a skilful ophthalmologist, is winning the affection and esteem of many of Bavaria's poor by his gratuitous services in their behalf. His wife, the Duchess, is his able assistant, and "performs the part of nurse and general benefactor."

COMMENT UNNECESSARY.—Raw ham and bologna sausage had for years been favorite articles of diet with Joseph Palmi, aged thirty-four years, of New York. He died at Bellevue Hospital of trichinosis. His muscles were literally alive with the parasitic worms.—*Daily paper.*

TO avoid catarrhs a family journal advises its readers to "keep the mouth shut." It occurs to us that certain other complaints might often be avoided by the same method, such as epistaxis, and ecchymoses about the eyes, and law suits, and razzle-dazzle, and matrimony.

THE Philadelphia Almshouse keepers have been granted a new trial, because the jury's verdict had "nothing to do with the case." It was much like that absurd termination of a trial one occasionally sees, in which the defendant is found innocent, but must pay half the costs.

THE *Ledger* suggests that Brown-Sequard is behind the times with his great discovery.

Similar medicaments have been sold here for a long time. See pictures of "before" and "after."

None genuine unless the proprietor's name is blown on the bottle. Beware of imitations!

DR. TODD, of Georgia, is quoted in the San Francisco *Bulletin* as saying that the average length of life in the United States is longer than in any other country, namely, fifty-five years. The truth is that the average length in the United States is shorter than in any other country, namely, twenty-three years.

SIX hundred and seven deaths in Philadelphia last week. While one hundred and twenty-eight deaths are recorded from cholera infantum, there are 27 children dying from convulsions, 5 from diarrhœa, 12 congestion of the brain, 6 debility, 2 cholera morbus, 1 colic, 1 dysentery, 18 inflammation of the brain, 18 inflammation of the stomach and bowels, 19 inanition, 1 jaundice, 53 marasmus and 6 teething, and out of this list there are probably large numbers who really succumbed to the same causes as those which induce the disease known as cholera infantum.

ACCORDING to a Pittsburgh physician the bowlegs prevalent in that city are attributable to the descent of the hills by young children, in whom the ankles yield to ease the strain on the limbs.

If this be so then the children in Newburg, N. Y., and other places on similar spots, ought to have "hillside" feet, caused by tramping along those shocking steeps.

THE Press has been inquiring into the gastronomic habits of the Philadelphia doctors, and the following items show them to be truly men of taste: Dr. S. Weir Mitchell likes fillet of tenderloin with mushrooms, Thomas Biddle and Leonardo Judd take kindly to goose liver, while Dr. Da Costa prefers calves' brains and seltzer, and Dr. Cleeman calls for curried lobster or broiled woodcock.

CALLAGIN: "Doctor, haven't you been attending on old man Gilfullaw?"

Doctor: "Yes."

Callagin: "How is he to-day?"

Doctor: "He is beyond the reach of medical assistance, I fear."

Callagin: "What! Is he dying?"

Doctor: "Oh, no. He's broke.

THE International Medico-Legal Society has formed a permanent organization as a result of a highly successful meeting held in New York last month. The President of the new Society is Clark Bell, Esq., of New York, and among the vice-presidents is the name of Prof. John J. Reese, of this city, whose life-long devotion to this branch of medical and legal learning is thus appropriately recognized.

MR. MUMM, whose name is sufficiently well known, has lately run foul of the California Grape Growers and Winemakers' Association, by saying that no good champagnes could be made in this country. Mr. Arpad Haraszthy, of the Association, maintains in an open letter to Mr. Mumm (*The Analyst*) that the latter in making such a statement manifests either remarkable ignorance or mendacity.

AMONG Chinese remedies are tiger's blood, ground blood, bear's gall, asses' glue, tree bugs, elephant's gall, fossil crabs, fossil teeth, fowl's gizzard, "insects of nine smells," Job's tears, cow hair, glass, rhinoceros horns, cow's knee, puff balls, dragon's teeth, straw, hedge-hog, skins, dried silk worms, snake skins, crab's eyes, horse tails, and centipedes. Compare a pharmacopœia of two hundred years ago before sneering too loudly.

A MEMORIAL TO PRESIDENT FETTER'S WIFE.—A room in the Medico-Chirurgical Hospital has been handsomely furnished by the pupils of Girls' Normal School as a memorial of Mrs. George W. Fetter, wife of President Fetter, of the Normal School. A handsome crayon portrait of the late Mrs. Fetter is given a position of prominence among the pictures. The room was tendered to the Hospital by Misses Sarah McBride, Helen Dodge, Georgia B. Palmer, Anna Mull, and Anna Hume, in behalf of the school, and was accepted by Dr. Montgomery and Miss Atwood for the Hospital.—*Record.*

MANY of the papers are printing sensational accounts of the horrible tortures one suffers who dies by electricity, citing alleged cases in proof. It will be noticed that these stories come from electric lighting superintendents, who are trying to demonstrate that their currents are not suddenly fatal; but any one who is acquainted with the experiments performed in Edison's laboratory, will know how much credence to give to these reports.

A VERY important question has been raised as to the certainty of death following electrical accidents. In New York a dog which was pronounced dead by an expert is said to have recovered during the following night, after having been placed for some hours in the earth. In this case the current was so powerful that the wire had burnt an inch into the dog's flesh.

In case of accidents by electricity it is well not to give up efforts at resuscitation too soon.

A SICK woman in a railway train in England recently received her death through having her head struck, while it was out of the window, against a mail bag, which was suspended near the train in order to be caught by the mail van in the rear. The *Hospital Gazette* in relating the case, says that it will be very difficult to find a remedy for this danger. We know of a simple one: Put the mail van in front of the passenger coaches, as it is in this country.

A "PHYSICIAN of eminence," in London, is said to have called kissing one of the most common causes of the spread of disease, and to have also intimated that the practice itself is a disease. Indiscriminate kissing of babies and general promiscuous kissing is certainly dangerous and to be discountenanced, but we should dislike to see the "disease" altogether eradicated. Our theory is that we have to suffer a certain amount of disease in any event, and this being so, we prefer to acquire it in this way.

THIS year the direction of the athletic sports at the University of Pennsylvania was taken away from the students and vested in the Faculty. The result has been a phenomenally disastrous season in base ball, boating, etc. The base ball club went to pieces before the season was half over, after vainly seeking for a club it could best.

Better let the boys manage their own sports, and if they can make no better showing, send them back to their books.

THE Second International Congress of Hydrology and Climatology will be held at Paris, on October 3 to 10, at the Trocadero Palace. In addition to the regular work of the Congress, excursions will be made to Pierrefonds, Compiègne, Enghien, the Observatery at Parc de St. Maur, the City of Nancy, Gerardmer, Bussang, Luxeuil, Vittel, Contrexeville, Martigny, and Bourboune. Communications should be sent to M. le docteur F. de Ranse, à Neris (Allier), the Secretary-General.

Subscriptions for membership should be addressed to the Treasurer of the Congress, M. O. Doin, 8 Place de l'Odeon, Paris, with postal note of twenty francs.

THE practical unfitness of women as physicians appears to be demonstrated at the Philadelphia Women's Medical College. As the older members of the Faculty drop out their places are gradually being filled by men. When Dr. Bodley died her place was filled by a man. Dr. Dickson resigned, and instead of putting in Emily Dubois, a graduate of the school, fully competent to fill the position, Dr. Wm. Parish was selected. Dr. Marie Formad applied for the Chair of Pathology, vacated by her brother, but again the place was assigned to a man. The logical deduction is that the Women's College is unable to develop from its own graduates suitable incumbents for these positions.

A NEW hospital for women in Philadelphia is to be opened at the northeast corner of Forty-first and Ogden Streets. The new Institution is exclusively under the management of women, Dr. Elizabeth L. Peck being the Resident Physician. The West Philadelphia Hospital for Women begins its work with very limited funds, and the Managers hope for liberal contributions of money, furniture, old linen, carpets, dishes, cutlery, or anything that can be utilized in the work. It is expected also that generous help will be extended through annual subscriptions of sums of from $1 upward. The hospital begins its work on Monday in dispensary and out-door service, and will receive a few house patients for a moderate compensation, not yet being pecuniarily able to take charity patients in the house.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 30, 1889, to July 13, 1889.

MCPARLIN, THOMAS A., Colonel and Surgeon. Under the provisions of the Act of Congress, approved June 30, 1882, by direction of the acting Secretary of War the retirement from active service this date, by operation of law, is announced. Colonel McParlin will repair to his home. Par. 2, S. O. 157, A. G. O., July 10, 1889.

TOWN, FRANCIS L., Lieut.-Colonel and Surgeon, U. S. Army. Promoted Surgeon, with rank of Lieut.-Colonel, to rank from July 10, 1889. Vice A. K. Smith, promoted.

SMITH, ANDREW K., Colonel and Surgeon. Promoted Surgeon with rank of Colonel, to rank from July 10, 1889. Vice McParlin, retired.

CORSON, J. K., Major and Surgeon. Leave of absence for one month granted. Par. 2, S. O. 65, c. s., Department of the Columbia, is extended one month. Par. 1, S. O. 45. Headquarters, Division of the Pacific, June 24, 1889.

CHAPIN, A. R., Captain and Assistant-Surgeon. Leave of absence is granted for twenty-five days, to commence on or about July 2, 1889. Par. 6, S. O. 145, Division of the Atlantic, June 27, 1889.

GORGAS, H C., Captain and Assistant-Surgeon. Leave of absence for one month is granted, to take effect on the arrival of a medical officer to relieve him. Par. 2, S. O. 84, Headquarters, Department of the Missouri, July 3, 1889.

GIBSON, R. J., Captain and Assistant-Surgeon. Reports arrival July 2, 1889, at Camp Lewis, Fisher's Island, N. Y., in compliance with Par. 5, S. O. 133, Division of the Atlantic, which designated him as Medical Officer for the encampment (rifle practice) at Fisher's Island, N. Y.

PERLEY, H. O., Major and Assistant-Surgeon. Is ordered to accompany troops from Fort Wayne, Mich., to Gognac Lake, Mich , to encamp there with the Michigan State troop from August 8 to 13, 1889. Par. 1, S. O. 154, Headquarters, Division of the Atlantic, July 9, 1889.

PERLEY, H. O., Captain and Assistant-Surgeon. Is granted fourteen days leave of absence, to commence about July 14, 1889. Par. 2, S. O. 154, Headquarters, Division of the Atlantic, July 9, 1889.

BEALL, GEORGE T., Captain and Medical Storekeeper. Leave of absence is granted for two months, by direction of the Secretary of War. Par. 8, S. O. 148, A. G. O., June 27, 1889.

CHERBONNIER, ANDREW V., Captain and Medical Storekeeper. Will, in addition to his present duties, take charge of the office and perform the duties of acting Assistant Medical Purveyor in St. Louis, Missouri, by direction of the Secretary of War. during the absence of Captain George T. Beall, Medical Storekeeper. Par. 2, S. O. 151, A. G. O., July 2, 1889.

INES, F. J., Assistant-Surgeon. Will proceed from Fort Lyon, Cal., to Camp near Oklahoma City, I. T., and report to the commanding officer for duty, relieving Captain W. C. Gorges, Assistant-Surgeon, who, when so relieved, is authorized to avail himself of the Leave of absence granted him in Par. 2, S. O. 84, c. s., Department of the Missouri. Par. 1, S. O. 87, Department of Missouri, July 9, 1889.

BRECHEMIN, LOUIS, Captain and Assistant-Surgeon. Is ordered to Illinois National Guard, near Springfield, Illinois, during remaining portion of encampment. Par. 1, S. O. 159, A. G. O., July 12, 1889.

BALL, R. R., Lieutenant and Assistant-Surgeon. Leave of absence is granted for fifteen days. Par. 3, S. O. 87, Department of the Missouri, July 9, 1889.

Changes in the Medical Corps of the United States Navy for the week ending July 13, 1889.

WHITE, S. STUART, Assistant-Surgeon. Ordered to the Naval Hospital, Brooklyn, N. Y.

WHITE, C. H., Medical Inspector. Detached from the "Trenton" and wait orders.

NORFLEET, ERNEST, Passed Assistant-Surgeon. Detached from the "Trenton" and ordered to the "Monocacy."

AMES, H. E., Passed Assistant-Surgeon. Detached from the "Monocacy," proceed home and wait orders.

HARMON, G. E. H., Surgeon. Detached from the "Constellation" and ordered to the Naval Academy.

LOWNDES, C. H. T., Assistant-Surgeon. Detached from the "Constellation" and ordered to the Naval Academy.

WHITE, S. STUART, Assistant-Surgeon. Detached from the "Trenton," July 7, 1889.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service from June 10, 1889, to July 13, 1889.

FESSENDEN, C. S. D., Surgeon. To proceed to Cairo, Ill., on special duty, July 8, 1889.

LONG, W. H., Surgeon. Granted leave of absence for twenty-eight days, June 18, 1889.

AUSTIN, H. W., Surgeon. To proceed to Cairo, Ill., on special duty, July 8, 1889.

IRWIN, FAIRFAX, Surgeon. Granted leave of absence for ten days, July 6, 1889.

MEAD, F. W., Passed Assistant-Surgeon. Granted leave of absence for thirty days, June 24, 1889.

MAGRUDER, G. M., Assistant-Surgeon. Relieved from duty at Baltimore, Md., to report to the Supervising Surgeon-General for duty as acting chief clerk and attending surgeon, July 10, 1889.

GOODWIN, H. T., Assistant-Surgeon. Granted leave of absen e for thirty days, July 8, 1889.

Clinical Lecture.

NEURITIS.

(Delivered May 29, 1889, at the Orthopœdic Hospital.)

BY WHARTON SINKLER, M.D.

Reported by WILLIAM B. STEWART.

GENTLEMEN: The subject of my lecture this afternoon is neuritis, or, as its name implies, an inflammation of a nerve. It may be in one or all the nerves of the body, and is known as poly- or multiple neuritis. It has been recognized as a distinct and separate affection within the last few years. It may affect the sheath of the nerve or the substance between the nerve fibers. The causes are various, as from direct or indirect injuries. A dislocation of the head of the humerus will often cause a neuritis of the whole arm from bruising, or pressure on the musculo-spiral nerve, which is most common, and disturbs the function of the parts to which the nerve is distributed. It may also come from cold. Another form known as neuritis migrans occurs in the periphery of a nerve and goes to its main trunk, and may be due to a cut or other injury; a cut causes a violent degree, and sometimes induces intense constitutional disturbances such as fever, pain, etc. It may come from syphilis or metallic poisoning. Lead palsy is generally recognized as a neuritis, and the majority of physicians hold to this belief, but it is uncertain; I myself think there is no doubt of it. It was thought that it was more common in the right arm than the left, but I do not think that observations have confirmed that view. If you take the most common form, paralysis of the extensors, we find it due to injuries of the musculo-spiral nerve.

Now, alcohol taken into the system in undue amounts causes a peripheral or multiple neuritis, and this is the only form that is caused by it. Neuritis is more common from the use of alcohol than any other cause. Gonze states that it is most common in women, but I think that I have seen as many cases in men as in women.

Sometimes it comes on, in multiple neuritis, with weakness of the extensors of the hands, wrists, fingers and legs; and at the same time, there is some transient mental disturbance, and as it progresses all the muscles of the members and trunk are affected, and the patient ultimately dies of respiratory paralysis; but before death there occurs marked mental disturbance. The beginning is complicated by pain, tenderness, feebleness, formication, prickling, constant jagging and quite acute pain along the course of the nerve. Moist heat and hot water applied along the course of the nerve will often give relief. This form is mostly alcoholic, and if seen early enough, you can count on a recovery. The first indication is to stop the use of alcohol at once, even though it is difficult to keep it from them. The muscles should be treated with massage; electricity is not good in the beginning, except galvanism to the nerve trunk when there is irritation, but when the irritation is less you may use the faradic. As to recovery, you often have contractions and disturbed sensation for a short time.

Closely allied to multiple neuritis is an epidemic form met with in Japan, that presents the symptoms of ordinary neuritis. These epidemics extend for a great length of time, and many of the people die or are disabled by it.

Another form that resembles it is the leper's neuritis, where the sensory nerves are more commonly affected than the motor. Neuritis may involve all the nerves of the body. Swelling occurs with exudation in the sheath of the nerve or the interstices in the sciatic, due to cold, injury, or a cut. It may involve the peripheral nerves of the skin, as in erythema nodosa or urticaria nodosa, in which the nerves in that region are in the state of inflammation.

Neuritis is much more important than it used to be, for by a knowledge of it we now know many forms of palsies to be peripheral instead of central, as formerly thought. What condition of things do we find in the nerves? There is an inflammation of the nerve, with heat, redness, and swelling; the vessels of the sheath are considerably engorged and the sheath itself distended by an exudation. Sometimes this exudation is in the sheath and sometimes in the interstices of the nerve; sometimes in the nerves themselves, with degeneration. Something like leucocytes are thrown out in the nerves, and the axis cylinder undergoes changes as well as the nerve fiber. The myelin is broken up, and the intervals become longer. The connective tissue increases over the substance of the nerve, and nothing but a fibrous cord remains in its place.

The most violent forms of neuritis are in the upper extremities, and may involve the whole arm or a single nerve. When the head of the humerus is thrown out of place the brachial plexus is pressed on to a certain extent, and a consequent neuritis extends down the arm. The greatest trouble appears to come from the reduction of the dislocation. I have in mind the case of a man who had an old dislocation, and shortly after it was reduced he got a neuritis. There are great disturbances in the skin, which is swollen, red, *shiny*, or even bullæ or small vesicles appear over the distribution of the nerve, that will last for months or even years, as occurred for three years in the case just cited. Many have it as the result of a fracture, with the neuritis extending to the shoulder or the hand. This is a common cause of trouble even where you have a perfect union of the bones. In these cases we have a neuritis, migrans, and consequently very limited, as in the case I now intend to show you. This woman had a fracture of the humerus in the upper third two months ago, and was treated well, with perfect union of the bone. She was left with pain in the shoulder and stiffness in the shoulder-joint, and on examination I found that the deltoid muscle had escaped injury, but the supra- and infra-spinatus muscles were much wasted, showing that the supra-scapular nerve had been affected. Generally, the supra-scapular and circumflex are involved at the same time. The circumflex nerve is often injured, and it is a common thing to see wasting of the shoulder. Many have it in the musculo-spiral nerve, as in the case of a man who had a cut over that nerve, and when healed the parts were palsied. Pressure over this nerve in a drunken sleep is a common cause of neuritis. Lie down for a short time on your arm, or let it rest over the sharp edge of a chair for a short time, and it "goes to sleep," and you lose its power for a time, and if continued for a length of time neuritis results. Dr. Price had a patient in whom he had wrist-drop that occurred during etherization for an operation, in which the arm rested across the sharp edge of the table for several hours. The ulnar nerve is often injured where it passes around the internal condyle of the humerus, as by striking the "crazy-bone" or by pressure, and a neuritis is produced that lasts a long time. The symptoms are, first of all, numbness followed by the parts feeling as if asleep; loss of power of motion, and various trophic changes.

I have here a patient in whom the median nerve is involved. It is a case of long standing, and I wish to show the results. In June, 1887, this lady, aged 73 was a seamstress, but did not do much work for several years past; she was never very strong, and was easily tired. Her left arm began to be numb, followed by pain, swelling, and redness. Pain on pressure over the course of the nerves, especially felt in the fingers and hand, and in the median and brachial plexus. The result has been that the little and ring fingers were affected, and some of the redness and glossiness still remain. Has had supra-orbital neuralgia, but has been much improved by the use of electricity. At one time she could not use her hand at all. She was given ergot internally. This is a simple case of rheumatic neuritis. Occasionally you will see cases come on without any cause, as in the case of one who had been confined to bed for nine years, and on getting up had intense pain in the arm, with loss of power; swelling of the fingers, with red, glossy skin, and contraction of the fingers; no history of pressure or injury, but came on slowly of itself without any assignable cause.

We have a form of neuritis, as I said, that is ascending, and occurs as a result of injury or cold; quite common after cuts by glass. I have here a woman, who was cleaning a window last November and the glass broke and made a cut over the knuckles of her three fingers. The wound healed, and in three weeks she came in with inability to extend the fingers, and it was found that the extensors were cut. On February last the tendons were united, under antiseptic precautions, with complete union and free motion of fingers. In one week after the wound was healed she felt numbness and pain in her fingers. Here is a case, then, where the ulnar was affected and then the disease extended to the musculo-spiral and median nerves. Has constant burning pain and shininess on the hand, and the course of the nerves is painful to the elbow-joint. After faithful and prolonged treatment with massage and electricity she can use the hand, but the joints are still enlarged, red, and glossy, and her little finger is slightly flexed. These are the trophic changes that you hear of.

Sometimes the hand burns and pain extends to the shoulder. Injury to the ulnar nerve extends to the brachial plexus or other nerves. Do not be too hasty

in the use of electricity, as it will increase the trouble when improperly used. Use a weak, descending current along the nerves; heat, hot water, poultices, hypodermics of cocaine, and massage. Diagnosis is easy. Between a peripheral palsy of the upper extremity and a paralysis from a central brain lesion it is one of interest. Lack of disturbance of sensation would indicate that it was not a peripheral lesion—electricity also shows this.

The electrical conditions are, first of all, the muscles respond to the faradic current, and, if anything, the response is too ready. As the nerves degenerate there is loss of reaction, and it is not until this reaction of degeneration sets in that it is time to use electricity.

THE PROPER FOOD OF INFANCY AND CHILDHOOD,

AND NEEDFUL SANITARY ENVIRONMENTS.

By B. F. HART, M.D.,
BROWNSVILLE, MO.

SINCE a large proportion of the race die in infancy, it follows that whatever offers greater security to infancy and childhood and tends to throw around that stage of existence the protecting shield of scientific truth, must conserve a good purpose, and be in accord with approved medical work, which has for its object the prevention, abortion and cure of disease, and the prolonging of human life.

Much progress has been made in certain departments of medicine within the past few years; so much, indeed, that the obscurity through which disease has heretofore been seen, seems to be rapidly passing away and giving to the future of medicine an outlook as promising as the most sanguine dared to expect. But in the midst of this progression, however, there appears to be an evident retrograde in things pertaining to the welfare of childhood. Nature dictates certain food and sanitary surroundings for the child, which are at present greatly ignored. Shall the infant be deprived of the God-given right to draw sustenance from its mother's fount according to creative design, and have the salutary laws of its being set aside, is a question of grave import. Those who study it in the right direction and in the best interest of childhood, will deserve no mean praise, since it lies at the very root of the well-being of the race. In cities, especially, it would seem that baby foods without number, wet-nursing, cow's milk fresh and condensed, have to a very large extent superseded the good old time-honored way of nourishing the babe at the mother's breast. This is unquestionably wrong, and in direct violation of the first law of our being. Neither mother nor child can violate this law without paying the penalty, unless in rare and exceptional cases. He who created all things, adapting everything to a special purpose, must in the very nature of the case, have known what was best for mother and child, and so ordered it in creation. The female who wilfully refuses to nurse her young without a sufficient cause, deserves the severest condemnation, and is unworthy to wear that name dearest of all others and around which so many memories love to linger—mother.

Statistics abundantly show that women who nurse their offspring are infinitely better off in every respect. The risks of the lying-in period are greatly reduced. They are much less subject to all those diseases peculiar to the puerperal state; the womb contracts better, and involution takes place more readily and more effectually, and the long list of chronic female affections is reduced to the minimum. This is what might naturally be expected from a physiological and philosophical consideration of child-bearing. The lacteal secretion diverts the fluxion of blood from the womb where it has served its purpose; thus relieving the congestion and giving the parts a chance to assume the ante-pregnant condition. This is certainly a wise provision of nature, and may not be arrested with impunity. How short-sighted and inconsiderate on her own account must be the mother who would thus act, even should she have no regard for the welfare of her infant. And what may be said of the medical adviser who frequently recommends or tacitly acquiesces in such a course? That he has studied medicine to a poor purpose; and must meet a fearful responsibility at the bar of God when all these sacrificed little ones shall appear against him.

The mother's milk, then, is the proper food for every infant, and nothing should deprive it of this natural nourishment, unless the mother is suffering from some constitutional taint; such as consumption, mental derangement, cancer, scrofula, epilepsy, syphilis; or whose blood is so much impoverished as not to supply healthy nourishment, and the drain on her system becomes too prejudicial for her good. Rarely, a change may be required in a few cases, because the milk disagrees with the child, although nothing is apparently wrong. Such cases, however, are seldom seen, and may generally be remedied by changing the food of the mother.

Owing to overmuch physical exertion of the mother or the too free play of mental irascibility, the milk is rendered colicky or otherwise unsuited, and should be changed suitably by removing the cause. Again, unseasonable nursing is often a great worry and tax on the mother, and very detrimental to the child, subjecting it to disquiet and pain, and in too many cases producing downright sickness. It is believed that very few mothers have any regular or stated periods for nursing, which is quite necessary for the good of both mother and child. It seems to be taken for granted that when a child cries, nourishment is wanted. Too often its little stomach is already oppressed and unduly distended with food, and it finds vent to pain in crying. An infant should have the breast regularly about every four hours, and it will thrive well, be free from pain, and generally free from crying, unless it has been spoiled by too much handling or rocking. Such a child is quite a little treasure, and in the language of the poet, is a "well-spring of pleasure" to all the household. Overfeeding is no doubt a serious cause of sickness in infancy. In consequence of overfeeding the baby cries, and then is too often drenched with catnip and other teas, and

dosed with medicines which meet no indications and prove more or less injurious. It is a frequent habit in such cases to administer opiates in some form of soothing syrup, or alcoholic toddies, to quiet the child and produce unnatural slumber; and thus the round is continued days in and months out. Such a course can have no other than a bad effect on a nervous organism that is most delicate, and responds so readily to morbid impressions, to say nothing of consequent impaired digestion, which strikes directly at the seat of life, since the stomach is the laboratory upon which all the vital processes depend. While the child may live and grow under such treatment it is very obvious that its start in life is at a disadvantage, and it is not going too far, perhaps, to say that the current of its future may be sadly changed for the worse. Sometimes the infant is permitted to contract the habit of sucking its thumb, which is likely to affect it injuriously in several ways. In the act its arm rests across the chest and not unfrequently produces deformity of the same, to the great injury of its thoracic organs in after life; besides, through reflex or sympathetic action it is likely to cause an irregular and unnatural flow of the salivary and gastric juices, thereby impairing the function of digestion. This habit may have the effect also, to some extent, of pumping air into the stomach.

Through ignorance or want of attention on the part of the mother, the infant often suffers severely, diseased action sometimes being set up by arresting free respiration by the use of tight garments, and covering the head too closely with bedclothes to protect from cold, or in the use of nets to keep off flies; thus compelling the child to rebreathe its cast-off exhalations, and an atmosphere that to a large extent has already been deprived of oxygen, and consequently is unfit for use and very unhealthy. From this cause doubtless death reaps an abundant harvest from the infantile world. About the great sanitary laws applicable to infancy and childhood, the majority of parents are most deplorably ignorant, and a little sympathetic excitement only tends to increase that state of things.

A strong case in point came home to the writer many years ago. It was in the latter part of August. No rain had fallen for three months. Creeks had dried up, the ground was cracking, vegetation parched, and the thermometer ranged in the nineties, when a gentleman gave him a call to visit his child six miles in the country, and implored great haste, as he said the child was dangerously ill and might die before his arrival. He found a six months' infant at the bottom of an old-fashioned box cradle, wrapped up in three big blankets, with nothing but a part of its face and the little blue eyes to be seen. Its breathing seemed to be running away, and the pulse was too rapid to be counted. In answer to the question, why it was so wrapped, the mother said to prevent the child from catching cold; something not likely to happen under the circumstances, if it had been left naked on the ground all day. The child's wraps were removed, and it was placed on a pallet on the floor, where remaining an hour, its breathing, pulse, and temperature were found to be perfectly normal. Meantime, no doubt, the anxious parents thought they would have to send for some other doctor who would do something for the little sufferer.

To the utter astonishment of the parents, they were informed that the child was all right and needed no medicine; and none was given, although a better opportunity never happened to do a little humbugging and make a cheap reputation by administering some colored water. In those days many people thought medicine ought to be taken like pouring soot into a sink-hole; and as none was given on this occasion, the sequel came out six months after, when then father, in settlement, objected to a full charge. On being asked about the child's recovery, he said he had never seen one do so well. The question was put why he sent for a physician, and he said, to cure the child, of course. He was then asked if it were not done, according to his own showing, in a most satisfactory manner. Seeing that he was entrapped effectually, and after having it explained to him that although no medicine was given, in all probability the life of the child had been saved, since had it remained in the condition found a short while longer serious and perhaps fatal disease would have been the consequence, he took in the situation fully, and willingly paid the charge. This child, perhaps, had a touch of cholic, and the parents becoming alarmed at its cries, failed to exercise common sense, and instead of benefiting it by their attentions, were actually placing its life in jeopardy. The case may serve to illustrate a great many minor ones continually occurring in the practice of any physician in full business even at the present day, and but too plainly shows that people generally need a vast amount of education on sanitary matters with reference to the wants of childhood. Another grave error committed by parents, especially in the poorer classes, is allowing the babe to have a chair at the table and partake of the ordinary food of the family at too early a stage in its existence. It makes a good hand and does its best, but the food being wholly unsuited to its powers of digestion, cannot be used without telling to its disadvantage.

But, owing to death or unfavorable constitutional disease of mothers, or their utter refusal to discharge the motherly duty, many children have to be otherwise provided for, and hence, other plans of nourishing the baby have to be considered.

As a general thing, next in importance and reliabilty to the mother's milk comes that of the cow, given by the spoon or the bottle. The milk from the ass and the goat is said to approximate more nearly that of the human, but its use is not generally practicable. Statistics drawn from various sources prove that the feeding of cow's milk to infants gives better satisfaction than anything else, except the mother's milk. While this is true, the statement needs some qualifications. The mortality of infants fed in this way runs very high or reasonably low, according to the condition of the milk when given. Milk that has been drawn from the cow long enough to have undergone fermentative change does not meet the wants of infantile nature to the fullest extent,

and, indeed, it frequently becomes a source of disease, which may terminate in death. Just like other food, then, it makes all the difference in the world as to whether the milk is perfectly pure and in a healthy state, and more especially is this required for the delicate organs of children. With milk fresh from the cow, the child should be fed about one and a half to two ounces regularly every four hours for the first month, and afterwards the amount gradually increased. This milk should not have been drawn from the cow over four hours before it is used, diluted one-half with water that has been previously boiled, warmed and sweetened at the time of giving. Occasionally a little lime water added answers a good purpose when it is indicated.

In all methods of nourishing the feeding should be entrusted to the mother alone, or to some one interested by ties of consanguinity; for upon its faithful performance depends the fate of the child. The utensils used in feeding should be disinfected by boiling water at least twice a day. The want of attention to this simple requirement has caused the death of untold thousands of promising infants. The use of cow's milk under the most favorable circumstances is when it is given immediately after milking and before it gets cold, the sooner the better. Milk as it comes from the teat is the most perfect emulsion known, and is most easily digested; but in a very short time, almost immediately, the oil globules begin to separate, and no device of man has ever been able again to reëstablish the same relation, and consequently it fails to bring about, when digested, so high a state of vitalization. This has been demonstrated, time and again, by old people and others of enfeebled vitality using the milk fresh drawn, resulting in a wonderful change for the better, giving flesh, strength, and health. This requirement can only be fulfilled under favorable circumstances, but wherever practicable it will well pay for the outlay. Another circumstance of almost equal importance, is to use the milk from a healthy cow; one that receives comfortable treatment, reasonable exercise, fresh, pure air to breathe, plenty of good, pure water, and a nourishing mixed food suitable to her wants. No poor, unhealthy cow should furnish the milk supply to an infant under any state of the case.

It is believed that under such treatment as is herein outlined for child and cow, the mortality rate would be very little higher than in children who draw nourishment from the mother's fount. In cities, owing to the difficulty and the impossibility, in a large proportion of cases, of obtaining good, fresh milk, other plans are resorted to, with only partial success. Many use condensed milk, and a goodly number of children live; but this is a risky business, as it is impossible to tell the condition of the cows from which the milk was obtained, or how much care has been used to keep the milk pure and have it canned under the most favorable circumstances. Still it is better than no food. To aid digestion, it is the custom now-a-days, to some extent, to peptonize the milk foods, but for a healthy child with good milk this is believed to be unnecessary.

Wet-nursing is also used to considerable extent in cities, and if under auspices of the most favorable kind, it would probably be superior to cow's milk.

It is known, however, to those who have investigated the subject pretty thoroughly, that, as a general thing, it proves quite fatal to infants submitted to the trial. The objections come from many quarters. As a matter of fact, the death-rate of infants reared on this plan is very high. Most of those engaged in wet-nursing are professionals, who have their own babes put out to be fed on manufactured foods of various kinds, and nearly all such babes die from neglect and the want of proper food in a short time. These wet-nurses are of very unreliable character, and most generally rank quite low in the moral scale. Many of them are suffering from constitutional diseases of a bad kind, which makes their lacteal fluid undesirable, if not absolutely dangerous. They practice their calling for the money that is in it, without much regard for the welfare of the child entrusted to them, and from previous habits of life can have little sympathy with their enforced surroundings. The potency of opiates and alcoholic stimulants are but too well known to them, and they fail not to use that knowledge to drug their charge into quiet, and sometimes into the grave. This feature of wet-nursing is not overdrawn by any means, as has been attested by numerous instances which have occurred. Again, while their milk might be good for their own babes it does follow that it would answer so well for those of entirely different constitutions, physically, mentally and socially.

Children nursed in this way have had their tempers and dispositions radically changed from that of brothers and sisters nursed by the mother; and this has happened so often that its truth can scarcely longer be called in question. With the milk drawn from this source the child takes also the cast of disposition of its foster mother, which may go with it through life to its great prejudice. The loose passions and perturbations of mind to which these nurses are subject from their previous mode of life, make their milk unsuitable in quality and often quite unhealthy.

This plan of wet-nursing makes infant mortality double, in consequence of the desertion of two children by their mothers. There are exceptional cases in cities where a good wet-nurse may be found, and under the direct supervision of the child's mother all things work together for good, and in smaller towns and country districts this not unusually happens. Other mothers there are, who having become disgusted with adulterated cow's milk and the wet-nurse experiment, rest their faith in the various foods, so plentifully manufactured and extensively advertised at the present day. These foods are generally produced after the formulated thoughts of Baron Liebig, and while they appear plausible enough theoretically, their practical use often fails to meet preconceived expectations.

But allowing that infant foods are not all without merit, still they cannot take the place of human milk; besides, they are quite too expensive for the poor to use. Babies in cities, being emaciated to mere shadows on many of these foods, have been sent to the country and put upon cow's milk, when, presto!

the little fellows have new vitalized blood generated, take on flesh, assume a lively disposition; thus changing and transforming, in fact, the whole current of their lives. Wonderful was the display of foods and various compounds for the young and the old at the Exposition Building in St. Louis, on the occasion of the meeting of the American Medical Association in May, 1886, and doubtless the same display is made at each successive annual meeting. This remarkable exhibition for medical men to gaze upon, suggested the thought whether doctors and everybody else were not getting cranky on the subject. There is evidently a craze in this direction, perhaps a crazy fashion that is having its day.

If infant foods, proprietary and patent medicines shall continue in vogue with increasing demand, as appears to be the order of the day, a time will come before long when there will be little use for the mammary glands or doctors either.

Now, while this judgment is herein recorded against artificial foods generally, it is but fair and just to say that they differ greatly in value, some being almost worthless, or worse, and others serving a fairly good purpose, and may be allowable under certain circumstances. That there is quite a difference between the farinaceous (Liebig) and milk foods for infants, has been clearly shown from chemical analysis and fully demonstrated by clinical experience. So that when their use is determined on, it becomes a question of chosing the best. And since in cities it is most difficult to get good cow's milk and meet all the requirements of cleanliness and purity, and as wet-nursing comes high, with other objections, a dry food consisting of baked flour and sterilized dried milk partially digested, to which only water has to be added, would probably be the best substitute in a great many cases for the mother's milk. Under like surroundings cow's milk used alone should be sterilized before giving it to the child, by some economical process, preferably by Soxhlet's apparatus.

A very good substitute for these patent infant foods is boiled flour; in fact, there can be little doubt of its being infinitely better than many of them, when added to properly prepared cow's milk, especially if diarrhœal trouble exists. This flour is prepared by putting good flour in a small bag and keeping it in boiling water for two or three days, though it is unnecessary that the water shall boil all the while. The inner part only of the flour thus boiled should be used. The process of boiling makes it easy of digestion, changing some of it to dextrine. Added to cow's milk, a teaspoonful or two of this flour will subserve a good purpose. The question of infant feeding is one of paramount importance, because it strikes at the very foundation of human growth and vitality. Faulty nutrition in infancy leads to structural changes in the thoracic and abdominal organs, and tends to dwarf manhood and womanhood; just exactly what happens, as is very well known, to the young and grown-up of all animals under like circumstances. Under such conditions, individuals and nations are bound to lose prestige and go into a state of gradual deterioration. The great mortality of infancy presses this question to the notice in figures most alarming. One-tenth of all children born in this country die before the end of the first month; and in 1888, more than one-third of the children born in New York City died before the end of the first year.

This is a fearful mortality, and it shows that something is radically wrong in the nourishment of infants and in their environments as well.

True, mortality tables show that death does not reap so broad a swath in rural districts, the rate being only half as great; and it is owing to this fact that cities continue to grow and flourish in the face of such heavy mortality, since they unceasingly draw largely upon the fresh, active blood and vigorous constitutions of country life. The tenement-house system in cities does very much toward making this unfavorable showing for them in the death-rate. In addition, the heat, dust, impure air and water, the large quota of bacteria swarming on every side, and the continual prevalence of contagious and epidemic diseases come in for a large share of blame.

While not entirely as helpless as infancy, childhood and youth, in all its stages to maturity, requires watchful care and helpful interposition of medical and sanitary science.

The child, during these stages of youth, should be instructed through its parents that the use of alcoholic stimulants, narcotics, and tobacco are unnatural, supply no want in the system, and exercise a most baneful influence on the young; and that a habit is then formed through which these deleterious agents in after life, are but too frequently used to great excess, resulting in the most deplorable consequences to health, morals, mental soundness, and even jeopardizing life itself. Tea and coffee are commonly used by children and not without injurious effect. They would thrive and do much better on milk and water as diluents with other food. These drinks interfere with digestion and unduly stimulate the brain; and as nervous activity runs highest at this stage of existence, they are liable to do incalculable injury. Too much meat and too little fruit is given to children. The various cereals, fruits, and vegetables are the natural, proper, and most healthful diet for children; and this idea should be instilled into them when young, so as to make a lasting impression. The less meat they take the more healthy will they be; and abstaining therefrom, their prospects for a vigorous old age and a long life will be greatly enhanced.

It has been clearly established that many diseases come from meat-eating; and as time elapses many others, little dreamed of now, will be traced to the same source. Every day brings to light something new in this direction, and points with unerring certainty to the manifold dangers attending this indulgence. How important, then, to fix a contrary habit in childhood's young bloom! Equally important is it to teach a child moderation in the use of food, one of the great evils of to-day being intemperance in eating; and this should be indelibly impressed upon the minds of the young.

Not only is there a vast amount of gluttony in the land, but people generally eat too much and too often

for either comfort, health, or long life. The stomach should have sufficient rest between meals to come to the work every time with pristine vigor, and then night-mare and dyspepsia would be names soon forgotten. Coranro, the Italian nobleman, after he had been given up by his doctors to die at the age of forty because of previous excesses, subjected himself to the spare diet of twelve ounces of solid food per day, and comtinued it till he became a centenarian. No man ever enjoyed old age more happily. Free from pain, sickness, and despondency, he was ever buoyant in mind and body; and gives the most delightful experiences ever recorded of old age. Such a joyous experience of life may happen to others who do likewise. Children should form the habit and practice on it through life, of attending to nature's call to evacuate the bowels on the first intimation; and thus, in all probability, remain forever unacquainted with the harrassing troubles of constipation and hemorrhoids.

Practising faithfully on these rules, sleeping in rooms well ventilated and as high above ground as possible, taking frequent baths, enjoying to the fullest extent the free air of heaven and the glorious sunshine, with an endless amount of exercise, ought, and doubtless will, make of children healthy and long-lived men and women, just in accord with the original intention.

REVIEW OF PROGRESS IN MEDICAL AND SURGICAL ELECTRICITY.

By WILLIAM R. D. BLACKWOOD, M.D.,
PHILADELPHIA.

FARADISM IN SUBINVOLUTION AND KINDRED DISORDERS.

PARSONS calls attention to the use of faradism in uterine subinvolution and passive congestions. His extract in the London *Medical Recorder* does not give the particular method of application, but in my own practice I have found it necessary to apply the electrodes directly to the womb, and preferably by one pole to the fundus—the other to the cervix to prevent too much lateral diffusion.

Galvanism in Gynæcology.—Dr. Ford, of Utica, alludes (at the eighty-third annual meeting of the New York State Medical Society) to galvanism in tubal diseases, and instances cases of hydrosalpinx of great severity rapidly cured by galvanism. Many cases of metritis, pelvic cellulitis, and ovaritis, in which fixation of the organs took place from extensive adhesions, were relieved under currents of two hundred ma. Subperitoneal or mural fibroids did not entirely disappear in any instance, but all the growth was checked, and in most instances the tumor was reduced to very small dimensions.

The same results were obtained by Dr. Parsons in a uterine tumor, the character of which was not decided. Bleeding followed an attempt at aspiration, but none attended electro-puncture. The mass was reduced four-fifths in bulk, and had not returned in one year after treatment.

Extraction of Foreign Bodies from the Eye by the Magnet.—Laquer refers to the employment of Hirschberg's electro-magnet for the removal of steel fragments from the ocular ball, and urges care in its use to prevent undue laceration.

Hubbell records the notes of two cases in which steel was removed from the vitreous. It is important that a free path be afforded the foreign body should it have fallen below the wound of entrance, lest further lesion be caused by the drawing forward of the sharp fragment of metal.

In several cases known to myself broken fragments of needles and metallic splinters have been removed from the hands by exposure to the powerful magnetic field of dynamos at lighting stations, and some of the employes at these places are quite expert in this branch of minor surgery.

Electricity in lieu of Laparotomy.—Goelet gives his views in an extended paper in the New York *Medical Journal* concerning the substitution of either current, in many cases of pus-tubes, myomata, and pelvic depositions after inflammatory action, for the ordinary abdominal surgery. Whilst in the main his conclusions are correct, it is apparent that much of the absence of caustic effect in the vagina under high currents is due to insulation of the free surface of the electrodes by the materials used to cover them. Three hundred or more ma. in the vagina will produce caustic effect if the whole force passes, no matter what the covering of the electrode may be.

Electricity in Gynæcology.—Bradford refers to cases of dysmenorrhœa from stenosis as cured in six sittings under eighty ma. Menorrhagia gave way to galvanism in two instances and metrorrhagia in one, where a cure was established in three months without drugs.

In the absence of villous endometrium, I have, for three years past, found faradism superior to galvanism in hemorrhagic tendency, for the malady is generally due to flabby and enlarged uterus, which is rapidly and thoroughly condensed by induction currents.

Photo-electrical Ophthalmia.—Dubinski, of Kronstadt, has observed peculiar ophthalmic disorders in the case of thirty sailors who were constantly exposed to strong electric lights. A curious part of the phenomena is that the symptoms occur during sleep. The patient is awakened by intense peri-orbital pain, profuse lachrymation ensues, with severe photophobia. This lasts for an hour to three hours, and then sleep ensues. Next morning nothing is felt except the tired feeling of overwork. There is palpebral œdema, a venous retinal pulse, and hyperæmia of the papilla. The difficulty occurs only during sleep, either at night or in the daytime naps.

I cannot find any similar trouble, after careful examination, in any of our employes in this city. Men who are exposed here to constant arc light of high power do not thus suffer, and there evidently is something in the surroundings of these sailors, or constitutional defect not prevailing here.

Galvanism in Cancer.—Dr. J. Inglis Parsons, of Chelsea, England, has made some interesting notes on four cases of carcinoma of the breast in which strong currents were used. The doctor depends largely on the effect of suddenly interrupted currents, and does not appear to attach importance to the purely electrolytic effect of galvanism.

The advantages claimed for this method of treatment are as follows:

1. There is no destruction to the normal tissues of the body, and if recurrence should at any time occur, its progress can be immediately stopped, and the treatment repeated as many times as necessary. Life would by this means be prolonged indefinitely, provided that metastatic deposits had not occurred before the commencement of the treatment. So far, cases able to bear the full strength required have shown no signs of recurrence.

2. Patients are not obliged to lie up, but are able to get about on the day following the application.

3. The current can be passed through almost any part of the body, and thus arrest growths which could not by any possibility be otherwise treated.

CASE I.—August 15, 1888. A. L., aged thirty-eight, married, Family: four children; three miscarriages; last, three years ago.

Family history: Mother died from asthma; father, alive and well, aged sixty-four. No history of cancer in the family.

Previous history: Has never at any time had any abscess or swelling in the breast, nor had any difficulty in nursing. Seven months ago she suffered from shooting pains in the left breast, and then noticed a lump there for the first time.

Present condition: On the inner side of the left breast there is a hard nodule, the size of a walnut, and a second one three times the size on the outer side, infiltrating the surrounding tissue. On the skin of the areola a distinct tumor can be seen; the nipple is also retracted. In the axilla are three enlarged glands. She complains of shooting pains in the breast and down the arm.

Diagnosis: Carcinoma of the breast. Mr. Bryant very kindly saw this case for me, and confirmed the diagnosis.

August 23.—Operation: Ether was given, and an interrupted voltaic current, slowly raised to four hundred milliampères, was applied to the breast and tissue round in every direction. During the application the pulse became stronger, while respiration was not affected. At each make and break, the arm and shoulder were jerked up.

August 25.—No rise of temperature or discomfort followed beyond a slight feeling of *malaise*. The pain has all gone.

August 30.—Operation repeated.

September 15.—The glands in the axilla treated in a similar way, and she was sent home.

October 18.—No return of pain. The mass in the breast and the glands in the axilla are smaller and harder.

Februrry 6, 1889.—She still has no pain, and the condition of the growth remains unaltered. General condition excellent.

March 12.—Patient continues to be quite well.

The extreme height was six hundred milliampères in any of the four cases given by Dr. Parsons, but I have carried the force to an ampère in one instance of uterine cancer in which needles were employed in positive electrolysis. The patient was not unfavorably affected by the current, but having been captured by an enthusiastic gynæcologist, I lost her. Six months afterwards she was better, but had refused operative interference at his hands. One of Dr. Parsons cases of mammary cancer had heart disease, but she did not suffer from the current. In such an instance I would certainly use puncture in in high currents to avoid diffusion from large electrodes.

The details of the doctor's manipulation are not clear. He speaks of *interrupted* currents, and refers to the alternative change in polarity of the needles. Unless reversion by a proper switch was practised this could not occur, and electrolysis goes on at the polar regions notwithstanding preconceived theories on anyone's part. The procedure is certainly one suggesting full trial, for no evident injury can be done, and the idea of using the knife is so distressing to others as to prevent early operation.

The diagnosis in these cases is apparently correct; in fact, it was confirmed by competent surgeons in some of them, Mr. Bryant amongst others.

I believe that Dr. John V. Shoemaker, of this city, is now investigating this question, and a report will be given hereafter.

Electric Cataphoresis.—Dr. Frederick Peterson reported to the Academy of Medicine recently the results of a number of carefully conducted experiments as to the enhanced diffusion of drugs endermically applied under galvanism. He has shown the futility of the Adamkiewicz electrode, which a New England physician, not long ago, boomed so much. The drugs chiefly employed were aconitine, cocaine, and chloroform, and his conclusions are as follows:

The cataphoric action of the constant current is beyond doubt or question.

The use of the Adamkiewicz electrode or of chloroform for cataphoresis is altogether inadmissible.

My own experiments have been chiefly with cocaine and aconite.

With the former, or with the two combined, a deep anæsthesia may be produced in conjunction with the anode, sufficient for the relief of pains in superficial nerves, or for small operations—such as the painless removal of cutaneous growths, or the electrolysis of hair roots.

The anæsthesia may be made rapid by the use of strong currents—an advantage in neuralgias—or slowly produced with a current imperceptible to the patient.

Wherever and whenever the anode is employed for the relief of pain, its efficacy will be greatly increased by moistening it with a ten to twenty per cent. solution of cocaine.

Rubbing the skin with a little alcohol or chloroform, to remove the oil globules previous to the application, will hasten the effect.

He suggests the use of electric cataphoresis for other purposes than that of producing topical anæsthesia. Wherever, for instance, iodine is used as a local application over swellings or tumors, the galvanic anode will greatly add to the efficacy of the medicament.

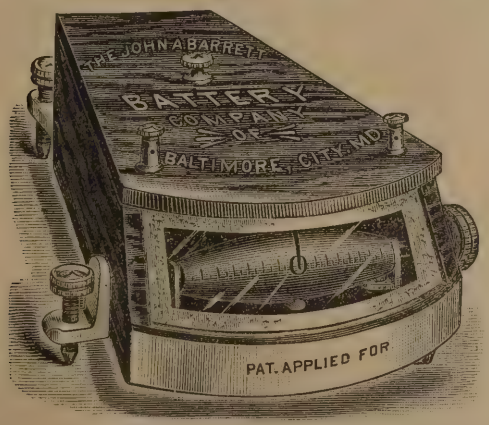
I have used cataphoresis for some time past in varied neuralgias, in sciatica, in earache and toothache; in otalgia a few drops of a solution of one grain of

atropia-sulphate to the drachm of water applied under galvanism to the canal, will relieve the pain in a few minutes in the ordinary attacks seen in children.

W. H. Walling writes concerning electricity in gynæcology in the "TIMES AND REGISTER," of June 22, basing his remarks upon a single case, and deducing from the experience gained the conclusion that currents of from two to thirty milliampères are sufficient for the reduction of myomata. He states that he never saw a case in which pain was not caused by mild currents, and inferentially decries the use of the so-called high application. It is a new idea in electrolysis to hear of "cauterization" by *twenty* milliampères for *three minutes*, but as the polar application was apparently indifferent (or changed from time to time), not much testimony could be secured on this point from the example noted. I have never, in many hundreds of cases, known of discomfort, let alone pain to be caused by fifty milliampères, and I often employ over a hundred without comment on the patient's part. He states: "I cannot coincide with those who claim that no pain is caused by such applications, agreeing rather with Dr. Martin, of Chicago, that if properly used they do not cause sufficient pain to require an anæsthetic." How many cases he bases his opinion on is not disclosed.

Electrical Illumination of the Bladder.—Mr. E. H. Fenwick writes concerning this in the *British Medical Journal*, and believes that the procedure is "performed rapidly and routinely in private or out-patient practice," and usually without anæsthesia. He also thinks that "cystoscopy is, if it be gentle and purposive, as free from risk as routine catheterism or sounding." This is encouraging, but young electro-therapeutists should not rush in frantically with a view of discovering the hidden diagnosis in difficult cases. They may come to a different conclusion, even if nothing else happens to them.

New and Improved Apparatus.—Messrs. Queen & Co. have added a condenser to the discharging-rods of their static-electric machines which increases the density of the direct spark decidedly. The device



consists of a metallic and vulcanite plate which is substituted for one of the balls, and it is readily put on or removed. The piece can be applied to any of their Toepler-Holtz machines, and it is inexpensive.

The John A. Barrett Company of Baltimore, Md., has added a new mil-am-meter to their list of apparatus, which has several advantages. Short, astatic needles are used, but the pointer of aluminum is four inches long, hence minute movements are multiplied. The magnetism is uniform and constant at any point of the country, as the system is not influenced by terrestrial magnetism. It has three independent reading scales. The interior connections are automatic and readings are direct, no multipliers being needed.

The uses of electricity are ever multiplying. Who could ever have dreamed that the electrical current manufactured by the public lighting companies conveyed along the streets would be switched off on special wires to go into the very mouths of the people! It is a fact. A man sits down in a dentist's chair nowadays and has his teeth repaired by the huge dynamos that are used for feeding the street lights. The patient lies back in a darkened room (if it is a dull day), an incandescent light illuminating the caverns of his mouth. The tooth is washed with water heated by electricity. It is dried and kept dry during the filling by air heated in the bulb of a little blowpipe by two red-hot platinum points. It is gouged and scraped, and scoured, and hammered, and sawed by little instruments that wriggle around on the end of the same electric current.

"Yes," says a dentist laughing, "and if you fall asleep during the operation we can just give you a little shock to wake you up."

Scientist Jansen, of the Mendon Observatory, has recently been engaged in examining the electric lights on the Eiffel tower, in the Paris Exposition grounds, with a spectroscope. He finds that at a distance of eight miles oxygen is present in a group of electric rays, tested after the manner of a solar spectrum. Prof. Jansen, therefore, concludes that this effect is due to oxygen in the atmosphere. There is no oxygen evident in a solar spectrum. The spectra of the sun are white.

Natural Electricity.—An extraordinary tale comes from Burmah. Mr. Ronald H. King, an electrician well known to the Burmese, while on a prospecting and shooting expedition in the island of Labuan, is said to have discovered a mineral from which electricity can be obtained without apparatus of any kind whatever. The mineral is described as being in the form of a black stone, of excessive hardness, and very great specific gravity, being nearly as heavy as platinum. A small block in the shape of an irregular cube, measuring 4.3 inches one way, by 5.2 inches the other way was brought away, and, on bringing it into the testing-room, a strong effect was noticed upon the galvanometer. At first it was thought that the mineral was an ordinary loadstone, but on tests being made, it was found that the force was more akin to that of an electro-magnet, and that a strong current would flow when the mineral was connected in a circuit. Further tests revealed that a difference of potential of forty-seven volts could be detected at the extremities, the internal resistance of the mass being twenty ohms. The block appears to waste away very slightly, leaving a slight gray powder upon the surface when connected up for some time. The electrician now uses the block to light a couple of incandescent lamps in his laboratory!

The Polyclinic.

PENNSYLVANIA HOSPITAL.

HIP-JOINT AMPUUATION.

ASHHURST presented a man about thirty years of age, whose left leg was to be disarticulated at the hip-joint to stay the progress of a malignant tumor developing in the stump of a previous thigh amputation. The patient had a history of being struck on the knee fifteen years ago, with a baseball, the sequence of which was the development of a fibroid tumor, which was removed. In 1887 a second slight injury caused the development of a tumor of a different kind, which was also removed and shown to be surrounded by a capsule. It appeared again in the diffuse form, when a high thigh amputation was performed. Malignant tumors, remarked the professor, are not infrequently found to be surrounded by a capsule. Cunningham, of Manchester, Eng., reported a case in which he had found a scirrhus tumor enclosed in a capsule. In performing the operation an abdominal tourniquet was used to control hemorrhage; pressure being made on the left iliac artery at or near the bifurcation of the aorta, and sufficiently strong to stop pulsation in the left femoral artery. The efficiency of this method of controlling hemorrhage was well demonstrated in that the operation was a comparatively bloodless one. The femoral artery was ligated before being cut, to guard against any mishap. A circular incision was made, care being taken to exclude every evidence of malignant growth in the parts reserved.

Pediculi Capitis.

For relief from these evidences of health (?) Longstreth recommends the application of soda solutions in the form of a poultice. The glue surrounding the egg which is fastened to the hair is dissolved by solutions of soda. The only objection to their use is that they change the color of the hair. But this should not militate against its use upon children. Baking or washing soda may be used as the needs of the case require. The hair should first be thoroughly soaked with a saturated solution, then it should be covered with a cloth saturated with the solution. The head should be then covered with oiled silk and bandaged.

In cases of typhoid fever, says Longstreth, where the mesenteries are involved, the application of fatty poultices to the abdomen is of immense value.

Persons having false teeth are more liable than those who do not have them, to swallow irritable poisons unawares. False teeth diminish the extent of sensitive surface.—*Longstreth.*

MEDICO-CHIRURGICAL COLLEGE.

REMOVAL OF UTERINE FIBROIDS.

THE patient was a colored woman, thirty-five years old, married, and had one child seven years since. Three years ago she noticed that her abdomen was enlarging, and it has distended steadily until the present time.

She also began to experience increasing trouble from pressure on bladder and rectum. There was a constant and annoying sensation of weight in the abdomen.

Upon making an examination, an irregular mass could be felt in the abdomen, extending up on the right side to the right hypochondriac region. This growth was movable.

Another irregular mass, felt below filled up the pelvis, and over the anterior surface of the abdomen, low down, could be distinguished a number of small nodular bodies. A diagnosis of multiple fibroid was made.

As the patient suffered so much from pressure symptoms and the weight of the mass as to render her unable to earn her living, she was very anxious to have the growth removed.

The operation was performed July 16, by Prof. Montgomery, assisted by Prof. Stewart, and Drs. West and Dorland.

When the patient was under the anæsthetic, the nodular character of the tumor and its irregularities could plainly be seen, on account of the thin and flabby abdominal walls. An incision was made, beginning one inch above the pubes and extending to just below the umbilicus. Several corkscrews were inserted into the mass above, and with some difficulty it was withdrawn down and out. As the growth was raised below it was found to be partly intra-ligamentous on the left side. The broad ligament was accordingly divided on either side, whereupon it was noticed that the cervix was long enough to form a pedicle. A rubber ligature was accordingly thrown around the cervix and the whole mass cut away. Pins were passed through the stump at right angles and Cintrat's serre-nœud applied to the pedicle just below the pins. Considerable difficulty was experienced in controlling the bleeding vessels on either side, owing to the large amount of raw surface exposed. After securing all these vessels, a drainage-tube was placed behind the stump, and the abdominal walls closed.

Since the operation the patient has had so little pain that only one dose of one-fourth grain of morphine has been given. The drainage-tube was removed on the third day. Her highest temperature has been only $100\frac{2}{5}°$ F.

JEFFERSON HOSPITAL.

CYSTOTOMY.

A MAN who for over a year had felt much pain, in the neck of the bladder, and who after urinating passed more or less blood, was thought by his physician in the country to have a stone in the bladder and came down to the hospital for the purpose of having this removed.

The surgeons were unable to find any stone, being able to make out only a ribbed or rugose condition of the bladder walls.

For the purpose of giving that organ rest, however, and to make a still more thorough examination it was thought best to perform a cystotomy. Nancrede entered the bladder by the infra-pubic route, having

made his incision in the median line. No calculus could be discovered, but digital examination disclosed a more or less papillomatous condition of the vesical mucous membrane. Several small masses were removed with the forceps. A catheter was then inserted through the wound into the bladder and the patient returned to the wards.

OSTEOTOMY.

This man presents a marked deformity of the left femur at its lower third, forward and outward. Six weeks ago his thigh was broken, and when he came in here, a few days since, he had a very neat plaster-of-Paris dressing on, and there was good union of the fractured ends; but, strangely enough, the dressing reached only up to the seat of the break, and hence this unsightly and troublesome deformity. The patient, a man, wishes to be relieved, so I shall rebreak that bone. I can do that either by first puncturing a small opening to the bone by means of a tenotome, drilling holes in the femur and then breaking it; or I may make a longitudinal incision to the bone just long enough to admit this chisel, and by the aid of a mallet, chisel the bone in two.

Instruments for both methods are here, but I shall choose the latter plan.

Having reached the bone with my chisel, I turn it at right angles to the incision and strike firmly with the mallet. This mallet I consider especially good. It is in the form of two cones with their apices together, and the handle connected at the slenderest point. These cones are filled with lead, making a good weight—one pound—in a small bulk, and also giving a sound as dull as that of a wooden mallet—an important point in private operations. After cutting partly through the bone in center and sides, I am able to break the remainder with the aid of several of my assistants.

The leg is now quite straight, and is not appreciably shortened. He will be put to bed with extension to the leg, and sand bags on either side for a few days, after which a plaster-of-Paris dressing will be applied. The operation has been done antiseptically, and I fear no untoward consequences.

For drainage I have put a few strands of catgut into the wound, and you notice that I take particular care to place them close together.

If the strands are allowed to be scattered, the effect of capillary attraction is lost, and they are of no use.

Moisture is also necessary, so I cover the wound with a piece of oiled silk.—*Nancrede.*

SALIVARY CALCULUS.

Here is a patient with an enlarged gland of the neck to be removed. Instead of making the ordinary incision, I shall make one in the line of future wrinkles, so as to make less deformity.

At the first cut I strike something hard and gritty, and you see I have removed a number of small calcareous particles; so that I believe we have here calculi in the submaxillary gland. Instead of cutting, then, I shall curette the rest of this, for in a place like this it is just as well to use the knife as little as possible, The facial artery is near this spot, and it would be no desirable complication to cut that.

—*Nancrede.*

PROSPECTIVE DIGITAL DIVULSION.

Barton brought before the class a little patient of about three years of age, suffering from obstruction of the cardiac orifice of the stomach. This obstruction is probably due to a tumor, detected by dulness on percussion.

The case was admitted by Barton to the wards for further observation; and if the statements made by the parents are verified, he purposes opening the abdomen, and if he fails to restore the caliber of the œsophagus by dilatation from the stomach or by removal of the tumor, he intends to perform gastrostomy.

ABSCESS OF TIBIA.

Here is a young man who has suffered great pain in the tibia for the last year, and I intend to trephine, with the expectation of finding a collection of pus. Upon trephining it was found that the tibia had undergone much thickening, and an abscess cavity was found that contained about an ounce of pus. The bone was then opened for some three inches, the whole length of the pus cavity, after which this was thoroughly cleansed and packed with mercurial gauze.—*Barton.*

WIRING A FRACTURE.

A case of ununited fracture was presented, which was of six months' standing. The accident had happened from the patient's having been caught in a rapidly revolving belt, and had resulted in four fractures of the forearm—two of the radius and two of the ulna, the latter compound. But one of the four fractures had united.

Barton first exposed the points of fracture, freshened with the saw all the edges, drilled and wired the fragments in position. The operation was performed antiseptically. The parts were at once put up firmly in a plaster dressing, and so far there has followed no constitutional disturbance whatever.

BANQUET TO TRAILL GREEN.—A magnificent banquet was lately given at Easton to that eminent and honored member of the medical profession, Traill Green, A.M., M.D., LL.D.

Many distinguished men were present and vied with one another in complimenting this aged and much loved man.

Jokes, merriment, good speaking, and good viands were the order of the evening, and everyone left much pleased with the happy event.

THE yellow fever scare in Brooklyn came at a particularly bad time for at least one of the principals—Dr. Bogert, who attended Dr. Duncan, the patient. The health officers quarantined Dr. Bogert, locking him up in a house, guarded by two policemen; where according to private advices he was perfectly furious, because at that very time he was looked for by a fair maid in Montreal whom he was to wed.

It seems now that after all Dr. Bogert was right; the disease was simply remittent fever.

HYDRO-THERAPEUTICS.

THE history of water as a remedial measure is replete with interest and affords the clearest demonstration of the instability of therapeutic propositions and the influence of prevailing thought upon the latter. From the day of Hippocrates, who wrote the Tract de usu Liquorum, and Asclepiades, who was dubbed "Psychioloutes," because of his advocacy of water in the treatment of diseases, some of the most eminent teachers and practitioners of medicine have been its warm supporters, and laymen, who have left their impress in history, have benefited from its practical application. Among the latter, in ancient times, it may be of interest to mention the Emperor Augustus, the poet Horace, and the philosopher Seneca. The tendency of the leading men in the past to form systems based upon some idea propounded and taught by themselves, has relegated many valuable therapeutic measures into the ranks of empiricism. Water has suffered more than all others, rising now and then to great popularity, only again to fall into desuetude. The literature of this remedy exceeds that of any other, except blood-letting, occupying twelve and a half columns of the Surgeon-General's index catalogue. So long as medical questions were surrounded by a philosophical nimbus, and speculation was the chief guide in the treatment of disease, so long did water experience the vicissitudes of other remedies. But since the utilitarian idea has become predominant and since it has become the chief aim of the physician to cure disease rather than to speculate upon it, the recognition of so-called empirical measures in therapeutics has become more pronounced. The advent of Priessnitz has, during the past half century, brought the practical results of hydro-therapeutics prominently before the lay public and through this channel before the medical profession. This is only a repetition of the history of other remedies.

Fortunately for suffering humanity several scientific physicians studied the methods of Priessnitz seriously, although the Paris Academy of Medicine condemned it in 1842. Lubanski and Fleury, in France, Van Housebronk, in Belgium, Schedel, Virchow, and, most enthusiastic and scientifically exact, Winternitz, in Germany, Gully and Howard Johnson, in England, are only a few of the men to whom we owe the combined clinical and scientific demonstration of hydro-therapeutics, which places the latter upon an enduring basis.

The advances made in the theory of fever, which began in Virchow's great work, have gradually led to more firmly establishing hydrotherapy in acute diseases, especially in typhoid fever. The works of Juergensen, Brand, Vogel, Naunyn, Glenard, Tripier, and others, have yielded the marvelous result, that the mortality of typhoid fever has been reduced from 25 per cent. to 2 per cent., and the end is not yet.

The preëminent therapeutic value of water finds eloquent expression in a series of clinical lectures, now being published by Von Ziemssen, whose graphic style, clear exposition of clinical points, and practical methods of treatment forcibly remind us of that brilliant clinician Trousseau. In the lecture (No. 10) on Tuberculosis, occurs the following passage: "I cannot finish the chapter without mentioning hydro-therapeutics, which here as well as in the already developed tuberculosis play an *extraordinarily important rôle*." In a lecture on Chronic Stomach and Intestinal Diseases (No. 12), he says: "I have frequently mentioned the thermic methods which were used with advantage in the cases described. I cannot here enter upon hydro-therapeutics in general but desire to impress upon you the fact that they act very favorably upon disturbances of the digestion and especially upon chronic stomach catarrh, atony of the mucosa lining, and of the muscularis, etc."

In the lecture on Scarlatina (No. 14), he says: "It remains, therefore, the most prominent aim to maintain as much as possible the power of resistance of the organic cells, and to spur the energy of the innervation. In the first rank stand here hydro-therapeutics, etc."

Similarly does Von Ziemssen express himself on its value in neurasthenia and other diseases. The testimony of so practical a clinical teacher cannot be disregarded. Indeed, the large number of institutions now in Germany, under the guidance of trained and scientific hydro-therapeutists, affords evidence of the regard in which the method is held by practical men.

It is singular that the practical turn of the Yankee, who is so quick to adopt everything profitable, has not yet asserted itself in this promising field.

The reason may be sought in the fact that "hydropath" and "water-cure" have become a stench in the nostrils of decent men. The empiricism of the practitioners who have endeavored to build them up as a sect, has alienated the profession and has thus

prevented the recognition of the true value of a scientific hydro-therapy.

Even the great work of Winternitz in English translation (Wm. Wood & Co., 1886), appears to have been overlooked by the profession, if we may judge by its fruits. A careful perusal of this scientific and practical exposition of hydro-therapeutics will surely rescue the latter from neglect and add a mighty weapon to the physician's armamentarium. We hope to present this subject frequently to our readers, and we anticipate a revival of hydro-therapeutics methods, which since its introduction by the father of medicine, legitimately belongs to its domain.

A TYPHOID SCARE.

THERE is an apparent attempt on foot to create a panic upon the subject of typhoid fever. Our position upon the subject of public hygiene has surely been stated with sufficient clearness and emphasis for all to comphehend it. But we have *no* sympathy with the movement in question, which we believe to be founded upon mistaken premises. The point of attack at present is the Schuylkill water; which might be better and might be very much worse.

The experience of Plymouth, and of many another localized outbreak of typhoid fever, shows that the materies morbi of this affection may exist in water and that comparatively large bodies of water or running streams may become contaminated to such an extent that every susceptible person partaking of the water in its natural state may contract the disease. But the history of these outbreaks proves entirely too much for the theory of the alarmists. The epidemic at Plymouth affected practically every person who was susceptible to the disease; and died out for want of material to work upon. In the smaller outbreaks recorded, where an infected well has been the source of trouble, the same rule has inured; every person being attacked who made use of the water for drinking.

This is our principal reason for believing that the drinking water in Philadelphia is not at fault. In Plymoth over one-third of the population was affected. The same ratio would give Philadelphia 400,000 cases! Instead of this, we have a little over a hundred cases reported last week; of which 11 proved fatal. It must be remembered that the drinking water is not the only means by which the germs of typhoid fever find access to the human body; though in epidemics it is the most important avenue. The air of infected privies is capable of imparting the disease. The use of bedding into which typhoid stools have been discharged, and the gases generated in sewers, into which typhoid stools have been thrown, are as capable of propagating this fever as is infected water. In a great city of over a million inhabitants, such sources of contagion may easily exist in number sufficient to account for every case of typhoid now reported, without resorting to the infected water theory, which fails because it proves too much.

The distribution of typhoid fever favors the explanation here given; for it is easy to see why the disease should prevail along a street lined with elegant mansions, all connected with the same sewer, when a small street in the rear, with a poorer class of residents, crowded more closely, with less breathing space, poorer food, less knowledge of domestic hygiene, should be free. The water-infection theory utterly fails to explain such anomalies; the sewer-infection theory renders it difficult to see how the facts could be other than they are.

With a palpable inconsistency, the parties who are railing at the Schuylkill water, say but little about the fact that the region supplied with Delaware water furnishes the larger number of typhoid cases. To those unacquainted with the Kensington district this would seem an argument in favor of the water-infection theory. But, even here, the facts are not in accordance with the histories of undoubted epidemics from water infection. The great sewers of Philadelphia nearly all pour into the Delaware River; and this sewage is carried up and down by the tide, so that at times it is impossible to avoid pumping this polluted water into the reservoirs. If the water be allowed to remain for a few days, the coarser impurities subside, and the water has a fairly good appearance and taste; though it is never comparable in purity to the Schuylkill water. In these subsiding reservoirs we find precisely the conditions for the cultivation of a general epidemic. The sediment of organic matter, disturbed only when the periodical cleaning occurs, offers a suitable nidus for the propagation of the typhoid bacillus. That a general infection of the people of Kensington has not occurred, is pretty good proof that the drinking water is not at fault.

Apart from this, there are other causes which may account for the prevalence of disease in this section of the city. The people are generally poor; their homes are unsanatory. Along the river front, many cellars are washed by the tide, which in some cases brings the sewage-laden water up to within a foot of the floor. Short sewers run directly down to the river, and the tide backs the effluvia up into the houses connected with these drains. Some years ago the writer made an investigation which showed that along the margins of the Cohocksink Creek the death-rate was far greater than in the rest of the Sixteenth Ward; and that the increase was in such diseases as phthisis, diphtheria, scarlatina, and cholera infantum. The creek has been since covered over; but Gunner's Run still remains, with its stagnant, inky stream, dotted with masses of offal from the slaughter houses, an open sewer in the heart of a populous district. Though a merciful Providence seems to have prevented the infection of the Delaware water with typhoid germs, it contains organic impurities of other varieties, in quantities sufficient to cause a great deal of sickness.

These causes of a generally sickly condition, together with the crowding of the population and the

general ignorance of sanitary laws, appear to us quite sufficient to account for the greater prevalence of typhoid fever in Kensington, without invoking the presence of Klebs' bacillus in the drinking water.

There is a method by which the dangers existing in the water, not only of typhoid fever but of every other affection the germs of which may be carried in water, can be prevented. It is absolutely innocuous, certainly efficacious, and so little costly that the poorest housewife may avail herself of it. All that is necessary is simply *to boil* the water which is used for drinking or cooking, and allow it to cool before straining it. Even a filter is unnecessary; and may possibly prove a source of danger.

When so simple a remedy is at the hands of everyone, requiring so little intelligence or skill in its application, is it not allowable for even the most earnest sanitarian to hesitate, before giving in his adhesion to the cry for an expenditure of thirty millions for new aqueducts?

Annotations.

THE TREATMENT OF WHOOPING-COUGH.

IT is a well recognized axiom in therapeutics that a multiplicity of remedies furnishes a fair indication of the incurability of a malady, and that the more loudly these remedies are vaunted the less efficient they are as a rule. Whooping-cough has long been an opprobrium medicorum. Unlike many other diseases of long duration, this disease announces itself in the most obtrusive manner. That its unmistakable note carries alarm to the stoutest heart of a mother, was illustrated a few days ago to the writer, who in approaching his office on his semi-weekly visit, was surprised by seeing four children and two ladies grouped upon the stoop. "There is a case of whooping-cough inside," was the anxious greeting offered by the alarmed mothers.

Amid the multitude of remedies proposed for this malady, it is difficult to steer clearly. A recent paper by Dr. Genser, reported in the *Wiener Klin. Wochenschrift*, No. 2, affords some interesting data, which will prove of value to our readers, because they represent a calm and judicial deduction from the material of a large outdoor pediatric service.

Referring to nasal insufflations of pulv. resin. benz., which Michaelis, of Hamburg, had found efficient in 75 per cent. of 300 cases, he states that he had applied them in thirty-six cases, without being able to confirm M.'s results. While our personal experience is in the same direction, and leads us to agree with Genser, that this is an unpleasant method which is sometimes followed by more severe paroxysms, and that the difficulty of applying it to young children is sometimes insurmountable, the fact remains that the small number of Genser's cases cannot be accepted as evidence against Michaelis' much larger experience. Insufflations deserve a further trial.

Of antipyrin, on the contrary, Genser speaks favorably from a trial of one hundred and twenty cases. He regards it as the most effective treatment at the present time. It was easily administered, it diminished rapidly the intensity and number of the attacks, and shortened the duration of the disease, especially in recent cases. Complications occurred less frequently. It proved quite innocuous, there being only one case of eruption from it. The dose should begin with one and one-half grains per diem for every year and should be increased to two grains if needed. Demme, Robin and Germain Seé have demonstrated in their experiments on the tissue changes during antipyrin administration, that it inhibits the reflex powers. It may in this wise diminish the number of the paroxysms.

The facility of administering antipyrin to children and its non-interference with the organic functions place it in the first rank of all our remedies, although all remedies are secondary to proper hygienic management, cleanliness, a plentiful supply of fresh air and good food.

We will be glad to receive reports on this remedy from our readers, provided they have been carefully recorded.

MILK sugar in cardiac dropsy is regarded by Germain Seé as the most reliable and least harmful diuretic. He attributes the good effects of a milk diet almost exclusively to the lactose. One hundred grammes (3⅛ oz.) lactose will produce an enormous diuresis, increasing the daily discharge in twenty-four hours to two and one-half liters, and daily overreaching this, until on the third day, four to four and one-half liters are voided. Milk sugar, therefore, removes cardiac dropsy surely and rapidly, and only fails if Bright's disease complicates it. It is usually well borne and may be continued for eight or ten days or longer, with intermissions. When cardiac dyspnœa co-exists, Seé resorts to iodide of potassium.

A MEDICAL INDEX.

IN this number will be found an index of the original articles published in our exchanges, especially those which are of interest to the practitioner. This index will be continued each week; so that the subscribers to the TIMES AND REGISTER will be enabled to see at a glance what papers have appeared during the preceding week on any subject specially interesting to them, together with the names of the authors. The exceeding richness of the literature of medicine renders it impossible for any journal to present even in the briefest abstract a tithe of the valuable papers which are published. This Index will enable our readers to send for copies of the original journal containing any article they want. This is experimental, and it depends upon our readers whether it will be continued. Our space is necessarily limited, and we wish to utilize it to the best interests of those who support the journal. If this Index meets with their approval, we would be glad to have them say so.

WHAT are all the abominations to be gathered from drinking water, as compared with those we give our children in cheap confectionery?

Letters to the Editor.

TREATMENT AND MANAGEMENT OF INFLAMMATORY DIARRHŒA IN CHILDREN.

THIS disease is one of the most fatal, and during our summer practice we generally run across a few little patients suffering with it, who exhaust our medical skill. So dangerous a disease should be carefully studied by every physician.

The first thing to be considered is the hygienic management. Such patients should be placed in a well ventilated room, or in late evening they may enjoy the outdoor air. I forbid placing them in a closed cradle for their resting place, as it is too heating and will exhaust them much sooner.

Next comes the dietetic treatment. Children suffering with an acute attack should be debarred from food for the first twelve or twenty-four hours, during which time, if they seem to be eager for drink, you may allow ice cold barley water every half hour. After this time has elapsed you may let them nurse, if they had previously been nursing, but, if bottle fed, you should withdraw the milk diet altogether and resort to wine whey, barley gruel, juice scraped from raw beefsteak, or some good prepared food.

If the child has been nursing I think nothing is superior to the mother's milk. If from any cause the child has to be removed from the mother's breast a wet nurse should be selected, and if that cannot be had I prefer fresh cow's milk. Cow's milk should be prepared as nearly as possible to represent the mother's milk.

If the stomach is very irritable, I prefer giving the milk peptonized.

Thirdly, the therapeutic treatment. On seeing my patient first, if the bowels are costive I give a cathartic; if they are moving gently and the stools are acid, I prefer as a cathartic Rochelle salts; and if they are alkaline I give castor oil; but if the bowels are moving very freely and my patient is much exhausted, I at once resort to my regular treatment.

In this I make opium my base and use adjuvants according to the reaction of the fecal matter; if acid, giving alkalies, and if alkali, giving acids. My experience has led me not to deal with the liquid preparations, and especially the weaker ones, unless my case on hand be exceedingly mild, or if my patient is over six months old. I use nothing but the powdered opium. The powdered opium is more constipating and more lasting in its effect than the liquid preparations.

In prescribing powdered opium I usually give to a child, one year old, one-fifth of a grain with ten grains of bismuth every two or three hours, watching carefully the effects of the opium on the system.

I never fear danger in giving opium to a child of that age, and persist in it, unless its pupil fails to respond to light, when I limit myself to the weaker preparations. While I make opium my base, I also give the chalk mixture, adding to each dose one grain each of salicylate of soda and saccharated pepsin. If I peptonize the milk I leave off the pepsin, giving it at intervals of four hours.

I believe in pushing the opium until you put the bowels at rest, and I think that no harm is done by arresting them as promptly as possible, if it is done in the acute stage of the disease, but after that has passed off, I think it harmful to force a check on an inflamed mucous membrane. For sick stomach, liq. calcis or a little soda may be added to the milk.

Local Treatment.—Stupes applied to the abdomen, composed of equal parts whiskey and turpentine, and occasional light mush or flaxseed-meal poultices, changed three times daily, will generally suffice.

This has been my plan of treatment for the past three years, and has proved in my hands most satisfactory.

A. L. HUTTS, M.D.

SALLYVILLE, S. C.

CINCINNATI LETTER.

DR. W. W. Dawson is congratulated on all hands by his many friends on his being able to preside at the recent meeting of the American Medical Association. His health had for some time threatened to prevent him from this honored duty.

Dr. J. T. Whittaker is spending the summer at Lake Chautauqua, as has been his custom for some time. By regularly visiting this resort he has built up a good summer practice there, and makes his summer's outing rather profitable.

Dr. N. P. Dandridge, after presiding over the section on surgery at the American Medical Association, at Newport, has gone on to Nova Scotia, where he will spend the summer, returning in September.

Dr. P. S. Connor, who delivered the Address on Surgery before the general sessions at Newport, will remain in the New England States till fall.

A case of Diabetes Insipidus, with favorable termination, was the subject of a paper read before the Cincinnati Medical Society, by Dr. Philip Zenner, Clinical Lecturer on Diseases of the Nervous System, Medical College of Ohio. He reported the case for the encouragement it might give in the management of similar cases, and for the therapeutic suggestions it may afford. The case was that of a boy twelve years old. He passed large quantities of urine, which had the appearance of distilled water. It contained neither albumen nor sugar, and had a specific gravity of less than 1001. Incontinence of urine compelled him to wear a rubber bag, and in this way the urine was measured and found to be about twenty-seven and one-half pints in twenty-four hours. The treatment consisted of electricity, antipyrin, and valerian. Antipyrin was given in seven and one-half grain doses three times a day, and powdered valerian root, one-half teaspoonful, three times a day. The electrical treatment consisted in the application of the galvanic current to the cervical sympathetic and to the spine, especially over the region of pain. The current used was of moderate intensity, the applications being made daily the first month, subsequently two or three times a week, each of about ten minutes duration. The improvement in the polyuria and the condition of the bladder was exceedingly slow, while other symptoms were ameliorated more rapidly, the appetite soon returning, and the pain entirely subsiding in a month or two. The improvement, though so slow

at first as to be scarcely noticeable from week to week, yet towards the last it was very rapid. He did not suffer from thirst, and drank very little. The specific gravity of the urine finally became normal, and he could hold his urine all night. As recovery in diabetes insipidus is extremely rare, especially in cases of a year's duration, it is very reasonable to attribute the cure, in part at least, to the therapy. He thinks all three remedies had a hand in the cure.

E. S. McKee.

The Inquirer.

ASSISTANCE REQUESTED.

I should like a little help in these two cases, for they have obstinately refused to yield to the treatment I have tried:

Case I.—A woman; thirty-eight years old; married. She complains of a continual drowsiness, saying that she could sleep all the time. There is a history of intermittent fever nine years ago, and this trouble, now growing worse, she has had ever since. She complains of nothing else, but has an anteflexed uterus. At times she will go to sleep while conversing. I have given her salines, quinine, strychnine, and the like, but without effect.

Case II.—A man, thirty-three years old, finds that his beard is growing white in spots about as large as a silver dollar. He has three or four such areas on his face; otherwise, he is in excellent health.

J. W. Frankhauser, M. D.

Shortlesville, Pa.

REPLYING to the articles of Drs. Saylor and Penney, on the Unpleasant Effects Following the Antifebrin, I would suggest that the cause of trouble in Dr. Saylor's case was too large a dose, and too low a temperature to indicate antipyretic treatment; in Dr. Penney's case, too frequent a repetition of the dose. The action of the drug begins in from one-half to one hour, reaches its maximum in about three or four hours; therefore, it is wrong to repeat the dose sooner than *three* or *four* hours, and if done bad or unpleasant results are sure to follow. I have used antifebrin quite extensively, and have had no unpleasant experiences to enter against it.

R. H. Endicott, M.D.

Oakdale, Cal.

Book Reviews.

Psychology as a Natural Science Applied to the Solution of Occult Psychic Phenomena. By C. G. Raue, M.D. Philadelphia: Porter & Coates, pp. 541, 1889.

Matters pertaining to the hidden and recondite are now no longer topics of discussion among an exclusive few dreamers, philosophers, metaphysicians, transcendentalists, and the like, but they are now subjects of conversation among the commonalty; and the words "psychics" and "psychology" are as common with the callow school boy and the pink and whitehigh school girl as "physics" and "physiology" formerly were.

One is liable at any moment to be engaged in a discussion as to the merits of therapy, and to be questioned on the difference between "phenomenon" and "noumenon," and on one's opinions about hypostasis, eschatology, avatar, etc.

All this is interesting, showing, as it does, that the scope of general reading is growing wider, and that the boundaries of general thought are widening.

Dr. Raue has undertaken in the first place to present psychology as a natural science, and in the second place to solve various occult phenomena by means of this science. His success we consider rather problematical, but at any rate he has written an interesting work, one that shows a careful study of his subject and a wide research.

The first part of the volume he devotes to an exposition of psychology as a natural science, and in the second part he applies this to the explanation of occult phenomena, such as mind-reading, hypnotism, thought-transference, and the like, making a very readable book.

Wood's Medical and Surgical Monographs. Vol. II, No. 3. Contents: General Orthopædics, Including Surgical Operations. By Dr. August Schreiber.

This volume ably keeps up the excellent standard held by these monographs.

It is written in a plain and clear style, and illustrated with a large number of cuts of various deformities, apparatus and instruments, so that the work cannot fail to be of interest and assistance to the practitioner who has anything to do with this branch of medicine.

Wood's Medical and Surgical Monographs. Wm. Wood & Co., Publishers, 56 and 58 Lafayette Place, New York. Vol. III, No. 1. July, 1889.

The July number of this excellent series is especially interesting. It contains the following papers: Cancer and Cancerous Diseases, by Sir Spencer Wells, Bart. F. R. C. S.; Cardiac Dyspnœa and Cardiac Asthma, by Dr. S. Von Bosch; The Influence of Menstruation, and of the Pathological Condition of the Uterus on Cutaneous Diseases, by Dr. L. Greillety; Tension as Met with in Surgical Practice; Inflammation of Bone; Cranial and Intra-Cranial Injuries, by T. Bryant, F.R.C.S.; Antisepsis and its Relation to Bacteriology, by Dr. J. Nendorfer.

The Old Hospital and other Papers. By D. B. St. John Roosa, M.D., LL.D. New York: Wm. Wood & Co., 1889.

This is a second and enlarged edition of the author's work called "A Doctor's Suggestions." Three new papers have been added.

The author says that the "central idea of the papers is an attempt to define and adjust the relations of the medical profession to the community which it serves," certainly an object much to be commended. The papers are interesting and readable, especially that on the "Coming Medical Man." Dr. Roosa gives him an authority and a power in the community that, judging from the advances made in past years, will hardly be reached before the dawn of the millenium.

PHYSICIANS' LEISURE LIBRARY. GEO. S. DAVIS, Detroit, Publisher. THE TREATMENT OF THE MORPHINE HABIT. By E. P. HURD, M.D.

This is simply a translation of one chapter of Erlenmeyer's great work on the morphine habit, but it is the chapter of greatest importance to us—that of treatment.

There is also appended a report of a number of cases treated by Erlenmeyer's method, for the further guidance of those who have to handle patients afflicted with this most obstinate habit.

PAPERS READ BEFORE THE MEDICO-LEGAL SOCIETY OF NEW YORK, from its organization. First Series. Third Illustrated Edition. New York: The Medico-Legal Journal Association.

The papers in this volume are of the most commendable character and will prove instructive and interesting alike to the physician and to the legal man. Such societies as these, where doctors and lawyers meet on terms of equality, to exchange views about this or that pertinent subject, or to discuss a paper on a topic about which all are concerned, cannot fail to be of the greatest advantage.

Those who cannot have the pleasure of being present at these meetings may, nevertheless, receive in great part the benefit of them by reading the Transactions. Such a paper, for instance, as The Sphere, Rights and Obligations of Medical Experts, by James O'Dea, M.D., cannot fail to be of value to any medical man who may be called to the witness box in that capacity.

THIRD ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF OHIO FOR THE YEAR ENDING OCTOBER 31, 1888.

Every year the reports of our different State Boards of Health are becoming more compendious and more valuable. The work of these boards cannot be too much commended and encouraged.

In this country the whole matter of such reports may be said to be in its infancy, but there are great possibilities and probabilities in store as to our knowledge of the conditions favoring or discouraging the rise or spread of the various diseases considered generally. These great probabilities make us deeply regret the short sighted political jobbery, noticed in some of the States, which tried to cut down to a starving rate, appropriations for a purpose of such vital importance to every lover of life and health.

Gleanings.

DR. KERR, of Rockford, Ill., has gone to Europe to study the treatment of hydrophobia.

DR. D. A. CHEEVER who has resided in Peoria, Ill., since the war, is going to take up his residence in Champaign, of that State.

DR. LESTER E. SHOCH, No. 1922 Diamond Street, Philadelphia, was last Thursday appointed by the Director of Public Safety, a Vaccine Physician of the Twentieth District, comprising the Thirty-second Ward.

DR. HARRY BAILEY returned to his home in Pekin, Ill., from Europe where, for a year, he has been visiting the large hospitals of London and Dublin.

CAIRO, Ill., has erected a handsome monument to the memory of Dr. Roswell Waldo, at Mound City, in recognition of his services in the yellow fever epidemic in 1878.

DR. J. F. FOX, formerly of Troy, but now a resident of London, and a member of Parliament, will take up his residence in this country again, either in New York or Albany.

DR. J. H. PHILLIPS of Preston, Minn., has been appointed a member of the State Board of Health, *vice* Dr. Hand of St. Paul, deceased. Dr. Phillips is a very popular physician, and was a member of the last legislature.

DR. T. W. BATTLE, an old and highly respected physician of Columbus, Ga., died at his residence Sunday, June 16, after an illness of considerable duration. The deceased was seventy-three years of age and leaves a wife and eight children.

THE medical board of pension examiners in Dubuque, Ia., now consists of Drs. M. H. Waples, J. S. Lewis, and George A. Staples. The latter was appointed to succeed Dr. M. E. Connelly. The board now consists of one Democrat and two Republicans.

THE semi-annual meeting of the medical society of Fulton county, New York, was held at Gloversville, Tuesday, June 18. Modern Treatment of Wounds was the subject of a paper read by Dr. F. Drury, of Breadalbin. Dr. W. C. Wood read a paper on Lazy Therapeutics. Miss M. Helen Cullings was admitted to membership.

OBITUARY.—At a recent meeting of the County Medical Society of Dansville, N. Y., a tribute to the memory of the late Zara W. Joslyn, who died April 25, was read. Dr. Joslyn was born in Cayuga, N.Y., November 6, 1815, and was graduated at Castleton, Vt., Medical College in 1842, and was very much respected.

DR. ISAAC W. MARTIN died June 20, at his residence, at Des Moines, after an illness of three weeks. Dr. Martin was born in Tippecanoe County, Indiana, November 11, 1838. He has been county physician and was for a time connected with the medical department of Drake University. He leaves a wife and one son. He was a prominent society man.

THE Coroner's jury of Clay Center, Kansas, brought in the verdict that the killing of J. P. Wellington, of Wichita, a St. Louis drummer, by Dr. J. P. Stewart, was justifiable homicide. Wellington was attempting to break up the family of Frank Head, whose wife was Dr. Stewart's daughter. Upon being encountered in the street he was first caned by the irate physician and then shot through the brain. The doctor gave himself up, but has since been entirely exonerated.

INDEX TO VOLUME V.

Original Lectures.

Chorea, L. Harrison Mettler, A.M., M.D., Philadelphia, Pa., 172
Clinical lecture, J. Wm. White, M.D., 361
Epilepsy, L. Harrison Mettler, A.M., M.D., Philadelphia, Pa., 241
Locomotor ataxia treated by suspension, Prof. Charcot, 292
Medico-Chirurgical College — medical clinic, Frank Woodbury, A.M., M.D., 289
Study of heart disease, John Aulde, M.D., 363
Tar and apomorphine in the treatment of winter cough, William Murrell, M.D., F.R.C.P., London, 169
Treatment of Urethral Strictures by electrolysis, Robert Newman, M.D., New York, 337

Addresses.

Argument for commutation of sentence. Case of People *vs.* Sarah J. Whiteling, Alice Bennett, M.D., 265
Ninth inaugural address, Clark Bell, Esq., 217
Some phases of cancer, Thaddeus A. Reamy, M.D., Cincinnati, O., 313
Valedictory address to the graduating class of the Medico-Chirurgical College, James E. Garretson, A.M., M.D., 317

Correspondence.

Allegheny County Medical Society, 65
Cases which trouble us, 376, 328–186

DIETETICS.

ON THE CHEMISTRY OF FOOD.

(Delivered at City Hospital, March 29, 1889.)

BY J. T. McLAUGHLIN, M.D.,

SPRINGFIELD, O.

LECTURE II.

IN preparing these lectures on dietetics, I am in the condition of the man with an overloaded stomach, having too much matter on hand to digest properly.

To understand dietetics intelligently, and to appreciate the value of foods, as well as to apply them in practice, it is essential to be at least somewhat familiar with the various tables, given by standard authorities.

1. The chemical analysis of starch, as found in different foods.

2. The percentage of such starch.

3. The proportion of sugar.

4. The percentage of oils or fats.

5. The chemical composition of such oils or fats.

6. The complete analysis of the composition of the various articles of food.

7. The nutritive proportion of different kinds of food.

8. Tables devoted to nitrogenous or tissue-making foods.

9. Others giving the carbonaceous or heat-producing foods.

10. Others calling attention to the foods in which the tissue and heat-making elements are largely blended.

11. Comparison of animal and vegetable foods.

12. With these we connect, of course, the various tables showing the time in which articles of food, as a rule, are digested.

Now, here, in the tables alone, is a sufficiency of matter, which, if presented in condensed form, would occupy the time of several lectures. Hence my allusion in the opening sentence. As these tabular statements, highly important as they are for close and earnest study, contain dry details, which can only be appreciated by comparison and prolonged attention, you will agree with me, that an occasional reference to them during this series of lectures will be amply sufficient.

Aside from these tables, which are the scientific guides, some other points deserve our attention, as preliminary and inseparably connected with the entire subject of dietetics.

1. The manufacture and preparation of articles of food. Leaving out the adulteration of foods, so reprehensible and injurious, we find that in other respects a diversity of opinion exists as to the proper manipulation of wheat, oats, barley, corn, etc. Now, while in ordinary flour any deficiency can be readily made up in the case of healthy persons by the addition of other foods, this is not so readily done in the case of the sick, or where the action of the stomach is weak. The tendency of the profession, therefore, is to demand what are called "health foods." Now,

while it is true that some of these productions are worthless, being thrown on the market by unscrupulous men for the sake of the money that is in them, it is also true, that scientifically and experimentally the theory and practice are correct. If we examine the tables and consider the condition of patients under treatment, the necessity and decided advantage of such prepared foods become apparent.

Now, without a desire to discriminate unfairly, or to do injustice to others who also prepare good foods, let me select two manufacturers to serve as an illustration of my meaning. Take, *e. g.*, the prepared infants' foods, and, according to the analysis of Dr. Bonn, of Germany, the American preparation of Carnrick's soluble food stands first on the list in view of its chemical composition and value, as regards both digestibility and nutrition. Its apparent superiority consists in its combining the flesh, heat, and bone-producing properties with easy digestion; for, to facilitate the latter, the milk introduced is previously treated with pancreatin, thus making the casein more suitable for feeble stomachs. The chemistry involved is happily applied.

Again, take the health foods prepared by the Sanitarium Food Co., and we have those that, in the very nature of the case, are admirably adapted for use in our practice. Thus in their "granola," prepared from wheat, oats, and corn, by long continued moderate heat and other processes, the starch and gluten are changed into already partially digested food, forming a concentrated article. In "wheatena," composed exclusively of wheat, and containing a large per cent. of gluten, we also have a partially heat-digested food, the starchy matter being converted into dextrine and dextrose, making it both agreeable to the taste and readily assimilable. And so with other preparations, among which I notice what they designate as "diabetic food," whose characteristic is, that it is chiefly formed of gluten, designed as a substitute for bran bread, lean meat, etc., in diabetics.

These references are amply sufficient to subserve my purpose. The medical journals are flooded with advertisements of such preparations, thus indicating the trend in this direction, and that the chemistry of food scientifically developed is professedly the fundamental basis of all such manufactures and preparations.

Let me say a word respecting the much abused superfine wheat flour. Now, it is true that this is largely composed of starch, and if this were the exclusive diet it would be comparatively a poor one; for we require not merely food-derived energy or heat, but also the flesh and bone forming elements. But let it be observed, to avoid extremes, 1, that bread made of such flour is not used exclusively as a diet; 2, that it contains essential ingredients; 3, that proper baking, forming a good crust, largely converts the starch into other materials; 4, and that sufficient mastication with the saliva in its marvellous quickness of action, changes the remaining starch into sugar. The baking process, thoroughly performed is the essential part; for the palatable and nourishing qualities of bread crust, and its digestibility, have been fully recognized by experienced nurses.

2. The position can be rightfully assumed that the digestibility and nutritive value of foods largely depends on the cooking. It may be somewhat humiliating to the physician, prepared with his long list and nomenclature of high sounding drugs, to confess how largely he is dependent upon the associated help of the good cook, but it is, nevertheless, the truth. A good physician with a poor cook, has a desperate case on his hands in low fevers, etc.; a poor physician with a good cook, has an invaluable ally to make up for his deficiencies; but a good physician with a good cook form a partnership that proves most highly beneficial, both in acute and in chronic cases, in the complaints of childhood and the diseases of men and women.

No matter how well selected may be the diet, if it is mistreated in the pot or oven, it loses its designed effect, and actually becomes, instead of a benefit, a positive injury. Here, in very critical cases, where life itself is with difficulty supported and sustained by careful dieting until a crisis is passed, the intelligent practitioner will exercise due caution and watchfulness.

Here, again, comes in the chemistry of food. In the baking process, already alluded to, we have by heat, not only the starch hydrated, but converted into dextrine and dextrose, and thus in part prepared for the action of the stomach, and in a state, too, that avoids the injurious fermentation. On the other hand, poorly made up and baked bread is both heavy of digestion and subject to such fermentation. One fruitful source of dyspepsia is poorly baked bread, and another combined with it is fried, instead of boiled, meats.

The intent of cooking is to prepare food for digestion, but if we are to judge from a great deal that is supposed to be cooked, the exact reverse of this seems to hold good. Even in so simple a thing as gruel for the sick we often have produced an extreme fatty "slop," weighted with spices to make it palatable, which would tax the digestive powers of a vigorous wood-chopper, and which, in the nature of the case, must prove hurtful to the patient. We may for special purposes select carbonate foods to supply needed fat and fuel, or nitrate foods for the muscles, or phosphate foods for the brain and bones, but injudicious cooking can utterly ruin the hoped for benefit to be derived from the same; and I venture the assertion, that the intelligent and discriminating physician can frequently trace his failure in successful treatment to the kitchen, where his knowledge and skill are counteracted by the ignorance of the cook. It should, therefore, not be regarded beneath the professional dignity of the physician to direct and investigate a work which is so intimately related to the health of his patients, and so fundamentally connected with success in practice.

The highest medical authorities are decided in their scientific and practical opinions on this very subject of cookery. Hence, we have establishments for the scientific training of cooks specially for the sick, and to impart this information generally, we have books devoted exclusively to "diet for the sick." These efforts are designed to reduce to prac-

tice in the kitchen the results of the laboratory in organic chemistry. The works mentioned contain many interesting facts, based on the conclusions of science, respecting concentrated foods of easy digestion, the chemical changes wrought by heat, the blending of oils with other material to avoid injurious effects, the observance of the elementary principles in the adaptation of food to various conditions and diseases, etc.

To illustrate the advance made in practical scientific cooking, we may take simply the making of beef-tea or extract. Science has shown that the old method of making beef-tea by boiling meat and water is a mistaken one. Dr. Holland, in his work, "Diet for the Sick," says: "The albuminoid or flesh-producing principle of meats is coagulated by hot water, and either remains in the meat or is skimmed off the extract as scum. The water has taken up the mineral salts and the flavoring principle, but is devoid of the nutriment commonly supposed to be dissolved in it. Soups and beef-tea are stimulating in their effect." One of the army surgeons prepared a recipe, which was issued by a circular order, for the use of the army. It is as follows: "Put a third of a pound of fresh beef, finely minced, into fourteen ounces of cold, soft water, to which four or five drops of muriatic acid and a little salt (from ten to eighteen grains) have been added. After digesting for an hour to an hour and a quarter, strain it through a sieve, and wash the residue with five ounces of cold water, pressing it to remove all soluble matter. The liquor will contain the whole of the soluble constituents of the meat (albumen, creatine, etc.), and it may be drank cold or slightly warmed. The temperature should not be raised above 100° F., as at the temperature of 113° F. a considerable portion of the albumen, a very important constituent, will be coagulated."

This is virtually the celebrated recipe of Baron Liebig. Here let me add this caution. This extract, as is readily seen, cannot be kept any length of time, but taking advantage of Baron Liebig's reputation, there is put on the market a "beef extract" called after him, which is not made after this formula, and, therefore, is condemned by eminent physicians because deficient in nutrient qualities. Dr. Dobell says of these: "It is important to bear in mind, that Liebig's extract of meat and other similar preparations contain very little, if any, nourishment properly so-called. . . . Their principal virtues belong to the class of stimulants. . . . When mixed with water they are excellent menstrua, in which to administer nutritive materials, such as eggs, oat meal, etc., but without such additions they are incapable of sustaining life for any length of time. Unless these facts are borne in mind, a patient may easily be starved unintentionally."

The chemical action and value of foods are apparent in every stage, and the more we learn of these the better we are prepared to appreciate their importance and enlist them in our practical service. How few, for example, realize the chemical action going on in the roasting of an apple. Some of the most agreeable, cooling, and delicious articles for the sick room are the different forms of vegetable jellies, or pectinacious foods. Now take, *e. g.*, the apple. In its unripe condition it contains but a small portion of pectine acid, but in the process of ripening the vegetable acids by their action produce pectine; for the malic, citric, and tartaric acids are enclosed in little cells, which this ripening action bursts open, so that these acids become diffused through the body of the fruit. Now, roasting or baking an apple is virtually only a very rapid artificial process of ripening, or, in other words, bursting the cells containing these acids and commingling them to form the compound, often so grateful and refreshing to the patient. The fire of the kitchen has a wonderful influence, conducive either to the comfort or discomfort, recovery or relapses and fatal issues of the patient, the invalid, and the well.

THE INDICATIONS FOR, AND LIMITATIONS OF, THE OPERATION

FOR THE REMOVAL OF THE UTERINE APPENDAGES.

By E. E. MONTGOMERY, M.D.,

Professor of Gynecology in the Medico-Chirurgical College, and Obstetrician to the Philadelphia Hospital.

THE enthusiasm engendered by a new remedy, or new surgical operation, is likely to lead to its applications in directions scarcely dreamed of by its originator; an application which very frequently the sober judgment of the future will not sustain.

Probably no operation has had a more widely extended application; no operation is fraught with more beneficial or injurious influences, as the indications for it may be correctly or incorrectly interpreted than that for the removal of the uterine appendages.

An operation that is capable of modifying the whole future of the individual, and her relation to those about her, should have its indications clearly set forth, and the limitations within which it should be performed distinctly outlined.

In studying the history of the procedure, we find it introduced and advocated upon three lines of indications:

1. To bring about the menopause, in what are known as the neuroses.

2 For the relief of symptoms arising from pathological conditions in the tubes and ovaries.

3. For the purpose of establishing the menopause because of grave and threatening disease in the uterus. While the general aims of the operation as here expressed are entirely legitimate, when confined to properly selected causes; it cannot be denied that the operation has been considered as indicated, and has been performed upon many women who might have recovered equally good health without mutilation.

The indications for operation may very properly be divided into physiological and pathological. The former comprises those done with a view to the establishment of the menopause without any reference to the presence of pathological conditions in the organs removed. The latter is done for the removal of diseased organs primarily, and may be partial or complete.

The pathological division may be classified as follows:

(*a*) The ovaries.

1. Inflammation, acute, chronic, suppurative (abscess) and perioöphoritis.
2. Displacement (prolapse, hernia).
3. Cirrhotic and cystic ovaries.

(*b*) The Fallopian tubes.

1. Inflammation, salpingitis.
2. Pyosalpinx.
3. Hæmato-salpinx.
4. Hydro-salpinx.
5. Fallopian pregnancy.

To the physiological class should be assigned:

(*a*) The uterus.

1. Uterine myomata.
2. Errors of development, absence or mal-development of the uterus with menstrual molimen.
3. Insuperable displacements, with severe nerve symptoms.
4. Insuperable obstruction to menstrual flow (may reside in the vagina).
5. Chronic metritis (areolar hyperplasia) with repeated abortions.

(*b*) The neuroses.

1. Mania, puerperal mania, menstro-mania, nympho-mania, etc.
2. Epilepsy, hystero-epilepsy, convulsions, cramps, dancing fits, etc.
3. Hysteria.

It is true that it is difficult to draw the line in making the distinctions herein mentioned. Many of the cases operated upon from a physiological standpoint, will be found to present pathological changes; but, when these conditions are so insignificant as to present no physical signs, and do not ordinarily produce symptoms necessitating operation, they may justly be classed as suggested.

In the development of the operation it has frequently been done as an empirical measure, without the indications either from a physiological or pathological standpoint being unquestionably marked. The physiological division has more probably afforded opportunity for the greatest abuse of this operation. All varieties of disordered nerve manifestation are likely to be exaggerated, preceding and during the menstrual period, which has led to radical operation when little was to be gained thereby.

The removal of the appendages in mania and epilepsy should be considered, as indicated, only when we can trace either in the origin or progress of the disease a close association with the performance of their function. It will not be sufficient to show that during the menses the individual is more likely to suffer with epileptic seizures, or to have an exaggeration of the intellectual derangement, but that the trouble either originated in menstrual disturbance, or in a marked degree occurs with the menstrual periods, and infrequently or to a slight extent only in the intervals. Where the disordered nerve condition can be traced to the influence of the sexual system, the removal of the appendages with the consequent cessation of the periodical congestion, has been attended with the most delightful results. On the other hand, where the operation has been done upon mistaken premises, the benefit has been unattained.

It is not to the credit of our humanity that a poor woman, so unfortunate as to be bereft of her intelligence, should be obliged to undergo the danger and discomfort of an operation of doubtful utility. Nympho-mania affords no hope of abatement through this operation. The ovaries and tubes, as have been well established in operations upon man and the lower animals, do not govern the sexual appetite, or the power to gratify it.

The orientalists recognized that the removal of the analogue of the ovary in the male, the testicle, did not destroy the desire or the ability for coition, and amputated the penis of the eunuch in addition to castration. Thence, the only plea for the operation in this form of disease should be to prevent conception. The writer has seen the appendages removed to arrest the practice of masturbation, but without the slightest favorable influence.

Hysteria, with the hydra-headed manifestations, has afforded the prolific field for the practice of this procedure; many cases, as experience has shown, could have been equally as effectually relieved by other plans of treatment, and have preserved their power of performing a woman's every function.

Certainly, in every such case, the operation should be held as a dernier ressort, and then performed, only after a full knowledge, on the part of the patient, of the influence it is likely to exert upon her future life.

The wisdom of establishing artificially the menopause should not be questioned, where the uterus is absent or faultily developed, with an effort apparent on the part of nature to establish the menstrual flow; in uterine displacements, non-restorable to proper position, and producing marked nerve symptoms; in cases of obstruction to the menstrual flow, congenital or acquired, whether existing in the vagina or in the uterus, when it is evident that these conditions cannot otherwise be readily and successfully overcome.

Chronic metritis, or the condition known as areolar hyperplasia, has been given as an indication for the operation. It cannot be disputed that in some cases of this disease, where, if anything, the state of inflammation exaggerates the susceptibility to pregnancy, and at the same time renders the uterus incapable of retaining and nourishing the developing ovum, the production of the menopause would add greatly to the comfort and health of the individual. The difficulty, however, of determining the cases in which it is expedient, and the danger of its abuse should render its performance infrequent.

The utility of the removal of the appendages for the arrest of hemorrhage and growth, in uterine myomata, has been too frequently demonstrated to be questioned. Many authenticated cases have been recorded, in which the operation has been followed by immediate arrest of hemorrhage, and subsequent marked decrease in the size of the tumor. It should be remembered, however, that the operation is not always followed by the menopause. Several patients operated upon by the writer have subsequently suffered from bloody discharge; in some amounting to hemorrhage; one has menstruated regularly for two years; another for six months. In consideration of this, it has seemed preferable, when feasible, to do supra-vaginal hysterectomy.

The pathological condition affords a field in which the indications for operation are more readily and accurately determined, and yet one in which the propriety of the procedure in individual cases may be questioned.

Suppurative inflammation in the ovary or tube should be considered a positive and imperative indication for the operation; the only question should be as to how soon the procedure can be accomplished. The condition is one of danger to the patient so long as it remains, far greater, indeed, than she would experience in its removal. This condition will be found complicated with chronic peri- or para-metritis, acute attacks of which it is frequently the cause. Indeed, it may be accepted as good practice, when a patient suffers from recurring attacks of either trouble, to make an exploratory incision with a view to the removal of the offending organs.

The presence of chronic inflammation in the ovaries and tubes is not necessarily an indication for operation. Many such cases readily recover under less severe and dangerous plans of treatment. Polk and Imlach have done good work in demonstrating that the separation of adhesions and shortening the broad ligaments by suitably applied sutures will prove curative in conditions that were supposed to positively indicate the necessity for the removal of the appendages.

The aim of the gynecologist should be to restore rather than to destroy diseased organs. It is not unfrequently found that pain in the ovarian region and its attendant reflex phenomena, is due to bands of adhesions between the ovary and loops of the intestines. The peristaltic action of the latter keeps the organ in a continuous state of congestion and irritation. Separation of these bands relieves the pain and discomfort, curing the patient as effectually as would the removal of the ovaries. We have a similar train of symptoms induced when the uterus is retroverted, and with the ovaries bound down by pelvic adhesions. Many of these cases do not require laparotomy to bring about a cure. Several have come to the writer's notice, where he has been able, by passing two fingers into the rectum and pressing up the cervix with the thumb in the vagina, to tear off the rectum from the uterus and set free the appendages. It is true that this plan of procedure is only applicable where the adhesions are of limited firmness. In extensive and firm adhesions the danger of laceration of the tube or the ovarian structure would be too great.

Oöphoraphy offers the preferable method of dealing with ovarian displacement, unless caused by marked enlargement from chronic disease.

The inflammatory adhesions, the complete destruction of function, and the reflex phenomena arising from the diseased condition, make the removal of the appendages advisable in the majority of cases of hydro- and hæmato-salpinx.

No one can practice abdominal surgery without appreciation of the great boon the introduction of this operation has been to suffering woman, and we cannot do better, in conclusion, than to urge:

1. That the operation for the removal of the appendages should be promptly performed in every case in which it is evident that relief cannot be otherwise secured.

2. It should be as a dernier ressort, where there is a hopeful prospect for restoration to health by less dangerous methods, or without the sacrifice of the reproductive function.

3. Its consideration should be dismissed in every case capable of restoration to health by other plans of treatment.

THE INFLUENCE OF MEDICAL JOURNALS ON THE MARCH OF SCIENCE.

(Read before the American Medical Editors' Association at Newport.)

By T. D. CROTHERS, M.D.,
HARTFORD, CONN.

IN January, 1889, there were published in this country and Canada, one hundred and forty-two journals which claimed to represent the science and art of medicine.

The influence these journals have on the march of medical science opens up a field of unusual interest.

The profession are every year depending more and more on medical journals for contemporaneous history, criticism, and guidance, and every year these journals are giving more accurate records of the movements of science, of the rise and fall of theories, of the evolutions and revolutions that follow along the line of medical scientific discovery.

The time has come when accurate conceptions and misconceptions of truth must seek a hearing through the press. Books are too slow, pamphlets are not read, the medical journals must present and defend the facts and theories continously and persistently. Any theory supported in books alone has little chance of attracting attention. No matter how absurd the theory may be, if it has an organ in the press, it will be heard. Hence, to-day, in this list of one hundred and forty-two journals we can trace a history of the empiric stage of science; we can see the superstition and credulity and the quackery which gathers about the birth of all truth; we can see the psychological growth and conflict of truth and error, and realize that all these journals of all degrees and kinds are unconsciously writing the history of the world's progress. We who are journalists, each hope that our work approximates to that ideal of absolute truth that we are striving after, above the levels of transient medical journalism, and along the very front lines of progress. The reality of our progress is in some degree realized by the constant appearance in the medical press of the latest discoveries and truths of medicine, and we feel that in some measure the march of science takes its shape and direction from our efforts. We who are the actors on this stage cannot fully realize our individual influence in the play, nor can we judge from the applause of the audience. We are too near each other, and our mental vision is too limited; but we can discern the imperfections of our work, and prompt each other from the wings. When some of our enthusiastic brothers find themselves overwhelmed with confusion by the discovery of having advocated some absurd theory, or defended some new remedy which proves to be inferior to cold

water, we can cover his exit with silence and charity. But when some of our brothers are attacked with dogmatism and have delusions that they are the central orbs of all science, or that other strange fatal disease, and its opposite, icy conservatism and frothy freshness, we put on garments of mourning long before life is extinct.

Bowing on the stage, or lounging in the wings, gives us some clear views of human nature and science. The search for truth and the effort to present it, brings out all the stars, the tragedians, the comedians, the supporters, and the army of figure heads.

As evolutionary optimists, we can catch glimpses of a progressive movement ever onward, although in our work this march of science seems like a confused advance and retrograde alternately. The incessant revolutions of theories and practices casts a shadow over our dogmatism and boasted exact experience, making it clear that the great drama of which we are actors and historians is beyond our present comprehension. The influence of medical journalism on the march of science, is also beyond our present comprehension. We can only draw some outline facts and apparent conclusions of this influence from a general study of the journals which claim to represent the science of medicine to-day. Of the one hundred and forty-two journals which began the year, death has claimed a certain number, but recruits have promptly filled their places, and it is safe to say there are no vacancies. But the long felt want is still urged. Journals come, and journals go, and the procession goes on.

Among the real scientific journals three distinct classes appear : The *general*, the *special*, and the *encyclopædic* journals.

The *general journals* aim to represent the entire field of medicine, to give papers and discussions covering every line of medical research. The claim of being practical and addressing themselves solely to the busy physician is often contradicted by the work. Such journals like the single volume text books fail, because the subject has outgrown the limits they would place upon them. A single volume text-book on practice or surgery can only be an outline view, more or less imperfect. So a general journal which attempts to spread the entire field of medicine before its readers, must do so in outline, and fail in many respects. The journals of to-day cannot do what was possible a quarter of a century ago. The heavy quarterlies are fast disappearing, and even the monthly is losing ground. Our journals must come weekly, and not far away the medical dailies will appear.

The journals that are taken by the general profession to-day must come often, and bring theory and practical experience; they must in newspaper parlance "boil down" every thing, and disseminate between the facts and fancies of authors. The general journal of to-day fails when its pages are loaded down with minute descriptions of disease and the exact action of remedies on the organism. It fails when the editorials are acrimonious and dogmatic. It fails when it dwindles into a newspaper of personal items and gossip, and apes the secular papers in tone and character. It fails when it assumes that medical science has advanced to the frontiers of positive truth in any direction. When the ideal general journal comes for the mass of physicians, it will be a weekly and daily.

It will be strictly impersonal and reflect the conclusions and results of scientific study up to the present.

It will avoid the ranks of dogmatism and credulity and follow a line of frank conservatism towards all science. It will aim to find not the practical alone, but the literal roads for the discovery of the probable facts and laws of science.

The ideal journal will arouse and stimulate further inquiry, and the reader will never be satisfied with the conclusions which it presents. The ideal journal will be an outline of what appear to be the best sustained facts concerning the problems of medicine. Such a journal must have concentrated power and force of editorial talent, to write the history of the medical advances truthfully and clearly to-day. Such work helps on the march of science and is growing more and more essential.

The *journals devoted* to *special fields* of medicine occupy a different position.

They give the observations of the picket-guards of science, the impressions of men who follow up a special line of research. They make the first surveys of new countries, which of course are imperfect and lacking in many details.

The probable facts and their conclusions are only tentative, and are given for the purpose of exciting inquiry and examination.

The specialists' journals are mapping out the topography of new countries, and making observations of its flora and fauna, which must be corrected by the armies of the rear, and more than all other journals do they influence the growth of science, and are in turn influenced by it. The multiplication of specialists' journals comes from the rapid widening of the fields of medical study; it shows clearly that the day for the general journal is drawing to a close; that like the single volume text-books, the science of medicine can no more be concentrated in one journal. In the twenty or more special journals that occupy the field in this country, this fact is more and more obvious.

From the smallest and most imperfect beginnings they are slowly and surely coming to "the front," and in the twentieth century the science of medicine will be studied in these journals. The specialist journals of to-day, with all their weakness and narrowness of work, are nearer and more influential in the real progress of science. They push on the exploration, from the mountain tops into the valleys, and along the river bottoms and plains of science. They map out the field for minute and exhaustive study, and give the results of individual work as no other journal can. Such journals cannot exist along commercial standards of value; they come in obedience to demands of a special audience; their readers are contemporarians, workers along the same lines of research. They can only live where science is most

aggressive, most active and most advanced. The general journal is of the past, the special journal is of the future. The one is a survival, the other is an evolution. The great text-books on the different branches of medicine are more and more the outgrowth of the work of special journals, the condensation and elaboration of views that have appeared first in such journals. On the growth and development of special journals, many of the great problems of medical science will depend.

The last class of journals that are prominent are the cyclopædial journals. They essay to give condensed summaries of the progress in all departments of medicine. Many general journals combine this feature with their work.

The ideal journal, or book, that will give a fair view of the medical progress of to-day is yet to come.

The attempts in this field are more promising than real. The readers of this class of literature and journals are filled with conflicting emotions concerning the near approach of a medical millennium, and the disappearance of the good old facts of our fathers and the humilating thought that all truth comes from over the sea. No true science in this American *Nazareth*. The ideal journal to occupy this field will be a great power in the evolutionary march. The ideal book giving a correct view of the progress is far beyond the journal or the special department in the journals.

These three distinct classes of journals appear either single or combined in all the medical papers that claim to represent the science.

Medical journals are slowly emerging from the stage of childhood, in which the personal views of its managers are more prominent and emphatic than facts of science; a stage in which the intense personality of certain men and colleges, or teachers, are fixed points about which all other truth must revolve. Every advance is judged from this point of view. Such journals resolve the science and art of medicine into fixed laws, that never change. They stand out in the great march as obstructive, like the Bourbon family, they never learn anything and never forget anything.

The *mutual admiration period* is *another phase* of the childhood of journalism. Journals of this class are passing away, and are very interesting psychological studies. The personal news items, and comments stage is another sign of youth in journalism. Sneering doubts, and fulsome endorsement of every new view of science are equally unscientific. We might go on and tabulate a long list of signs of youth and feebleness in the medical press, but a little higher view will show us that this is part of the natural history of the sudden birth of a small army of medical journals, who are each struggling to represent the whole or some part of this great ever-widening land of science.

Medical journals, like the science which it represents, are growths or evolutions from the lower to the higher, or devolutions from the lower still farther back. Medical advance is thoroughly revolutionary, and our best facts to-day disappear to-morrow, and give place to newer, wider views. Our journals ought to be histories of this restless change. Histories above all personal interest or motives, except to give the most probable facts and conclusions, sustained by all the evidence at our command.

As medical journalists we can never represent or influence science by allowing personal dogmatism or personal gossip criticism to appear in our work. We can never represent or influence science by endorsing an assumption that any one range of facts comprise the whole truth, or that the last and final truth is bound up in any theory. We can never represent or influence science by a partisan support or defence of any minute statement of disease or its exact laws, or the action of drugs on the system, or theories of physiology and psychology. *Medical journalism* to represent and influence science *must assume* the position of a judge, hear all the evidence, and then present to its readers those facts which seem best supported by research, theory and experience. Medical journalism to represent and influence science *must discriminate between* the probable and the improbable, between the statements and theories of men, who trust to fancy or to inductive reasoning, must discriminate between facts that are apparent or assumed, and insist that the record of sciences to-day have some support from the facts of yesterday. If this cannot be, the record must have an assemblage of probable evidence, that shall give it position and recognition.

Medical journalism to represent and influence science can never be a newspaper or a transient journal of the hour. It must rise to the level of the great laws which govern the evolution and dissolution of humanity. The individuality of the discoverer is as nothing compared with his discoveries. The truths of science require a higher standard of representation than the follies and accidents of life. While the one hundred and forty-two journals in this country that claim to represent medicine are in many instances sad reflections of so-called science, yet the American medical press as a whole is full of hopeful promise. While the quarterlies are doomed, and the monthlies are becoming more and more uncertain, the weeklies are growing in freshness and vigor. A new era is dawning for journalism. Both authors and editors must give the readers the clearest, briefest facts and evidence to sustain them. The theories and opinions of the fathers in medicine have of themselves no longer any weight, unless they have a direct bearing on the present. Papers loaded down with authorities are becoming more and more pedantic and absurd. There are no absolute facts in medicine, everything is relative, and good only for the present.

The world is full of working problems, which, like steps on a ladder, are means for higher and wider views of truth. In journalism we get the first surveys, in books, the corrected conclusions, good only for this day and generation.

Medical journalism reflects more and more positively the true spirit of the march of science in this closing century; not the march of science in Germany, France, or England, but the movement here in our own country, free from the blighting conservatism of the past, free from time-worn theories, and empiric conceptions that

are moss covered with age and respectability. Free to question every assumed fact, and demand the reasons for its existence.

Medical journalism in this country is growing stronger and more influential every year. We are gaining greater power with every advance, and realizing more clearly that medical science is an incessant search for truth, that widens with every step forward. Both as historians and explorers we are pressing on into the unknown, fully assured that greater facts and truths are yet to come from broad scientific work.

LARGE NÆVUS OF THE FOREARM—TREATMENT.

By A. C. W. BEECHER, M.D.,
Late Demonstrator of Anatomy, Jefferson Medical College.

MARGIE B., aged six months, has a large nævus upon her right forearm. In this as in all cases so young it is congenital, and has been increasing somewhat.

The tumor occupies the anterior face of the right forearm, extending from the metacarpo-phalangeal joint of the thumb upon its palmar surface across to the ulnar side of the carpus, and extending upward to within an inch of the bend of the elbow (at which point are several small vascular spots, and which probably would have eventually become merged into the general mass), laterally it extends from the outer radial edge of the posterior surface of the forearm, to the inner ulnar edge of the anterior surface, thus occupying one-half of the circumference of the forearm.

The tumor is elevated from one-half to three-quarters inch above the normal level of the contour of the forearm. There are several transverse depressions in the tumor due to the fatness of the child (which is very large and very well nourished). From pressure, the skin in one of these became excoriated, and a painful ulcer followed. The tumor is of a dark purplish color, and exhibits all the characteristics of its class. The painful condition of the ulcer, together with the deformity produced by the tumor, and the risk of an accidental laceration or incision into it producing alarming, if not fatal hemorrhage, make its eradication desirable, if not imperative.

In a consultation with the late Prof. Joseph Pancoast, he suggested the passage of strands of silk saturated in solution of chloride of zinc through the mass to produce coagulation of the blood in the vessels passed through and by the resulting inflammation and absorption, reduce if not obliterate the tumor. This method I adopted with some modification. I procured several sailmaker's needles about four inches long, had them curved for about two inches of their length from the point, the shanks being left straight. Arming each of these with half a dozen strands of silk and saturating them with the chloride of zinc, I passed them transversely through the base of the tumor at three points, allowing the concavity of the needles to curve over and fit the convexity of the forearm, entering the needles at the junction of the healthy skin with the tumor, and making the exit in like place upon the opposite side, being careful to ascertain that both the radial and ulnar arteries were beneath the needles, and not included in the ligature. Before the needles were drawn through, the arm was firmly grasped above and below the tumor to steady the extremity, and to check the circulation until the zinc in the saturated ligatures when drawn, had well acted upon the surrounding tissues, preventing hemorrhage and absorption of the zinc.

The ligatures once in position, their ends were brought up from the sides and tied over the mass just tight enough to depress the tissue under them, and by tightening these from time to time, I designed dividing the tumor into transverse segments; that accomplished, to sub-divide these by ligatures passed through their base parallel with the long axis of the forearm, and subsequently strangulate these with pins and ligatures. The combined action of the ligatures and chloride of zinc so thoroughly cut off the circulation, that the central portion of the tumor between the first and third ligatures sloughed out in a few days, leaving a healthy surface underneath, only the margins retaining the characteristics of the disease which were, later on, strangulated in small portions with pins and ligatures.

The surface left after the slough was removed was treated by skin grafting from the mother, and was partially successful.

The ball of the thumb was treated by taking a delicate straight needle with a single strand of silk steeped in chloride of zinc, and then passing it through the parts as in darning a delicate fabric, the silk remaining some two or three days; the vessels were occluded, and the discoloration was entirely obliterated.

There was but little constitutional disturbance, the surface cicatrized and contracted to less than half the original area with no impairment of motion, and is not observable unless attention is called to it. The dressing in this case was merely patent lint and oxide of zinc ointment. When the granulating surface appeared sluggish, it was stimulated by application of nitrate of silver.

This operation was performed when cleanliness, carbolic acid, and permanganate of potash solutions only were in vogue, and is only reported because of the method of dealing with the tumor, which was quite formidable of its kind, and the highly satisfactory result.

The darning process, I believe to be applicable to many of the red spots so frequently seen upon the face; it is safe, and not disfiguring, the cicatrices being slight. The chloride of zinc I believe to be the best of the agents which could be used as above described. A singular coincidence in connection with this case is, that when the mother was far advanced in the pregnancy of which this child was the product, the father while inspecting a new but not completed residence, fell down the stairs, severely injuring and bruising his right forearm; this accident shocked and distressed the mother very much at the time. Was the nævus the effect of maternal impressions caused by the accident to the father? It is at least a remarkable coincidence.

523 South Ninth Street.

RECENT MEDICAL CASES.

By HENRY A. RILEY, Esq.,
NEW YORK.

AUSTEN WILCOX, Esq., of Buffalo, in an address before the Medical Department of the University of Buffalo, on the Medical Jurisprudence of Insanity, summarizes the reform in our State legislation which he deems necessary, as follows: "If we can accomplish these three radical reforms in our methods of procedure: 1. To secure a competent tribunal to pass upon the single question of insanity. 2. To secure really enlightened and impartial experts on insanity to assist this tribunal. 3. To ensure that persons found innocent of crime on the ground of insanity shall be treated as insane, and sent to an asylum. Then it is safe to say that the law of insane responsibility for crime will be reformed and adapted to suit the new scientific conceptions of the age. It would be quite safe to leave in the hands of a tribunal so constituted, and acting under such conditions, the application of the broad ethical test of insanity, proposed by Dr. Bucknil: 'No act is a crime if the person who does it at the time, is incapable of not doing it, by reason of idiocy, or of disease affecting his mind.'"

This states, no doubt, the view taken by many lawyers, and by many possibly, most doctors. It is not, however, as we think, the view taken by most lawyers. The power to distinguish between right and wrong is considered by them the wisest and safest test by which to decide whether a person should be acquitted of a crime when the defense is insanity, or defective mental power. A person may seem to have little power over his will, yet if he understands that the act is wrong it is difficult to see why he should be acquitted on the ground of insanity.

The following is the lively way in which the *Albany Law Journal* comments on the recent proceedings in the Washington Irving Bishop inquest, in New York City: "But no matter whether he was dead or not, it is probably impracticable to hold them for manslaughter, but they should be punished to the extent of the law for an unwarranted dissection or autopsy. These indecent men were eager to be the first to discover the secret of Bishop's wonderful and exceptional mental power. To gratify their morbid curiosity and get ahead of the other doctors they cut up the victim's body before he was fairly cold, and without any more authority than they had to kill him.

"The thought that perhaps the poor man was conscious of their horrid preparations is one that humanity shrinks from dwelling upon.

"If this mob-law is the law of the City of New York, we advise strangers to keep away.

"If one's wife or child goes there and dies suddenly in the street—as Col. Chatfield, of Cincinnati, well known in this city, died there a few days ago—some superserviceable doctor 'in the interest of science,' may carve the animate remains without observing the forms of decency, or waiting to see if death has really supervened. If this kind of thing goes on there will apt to be genuine *rigor mortis* among the doctors. If Bishop had a father or a brother he would be excusable for clubbing them till they were cataleptic and hoping for another of their sort to come along and carve them up—all 'in the interests of science.' Dr. Clark Bell's coming convention would better look into this performance."

It will be remembered that the coroner's verdict at the inquest acquitted the doctors of any criminal act, but we do not know that they have been acquitted of the charge of improper haste in making the autopsy.

Christian science as practiced by most of its votaries is one of the most arrant humbugs of the day, and sooner or later some of its practitioners will find the inside of a prison their permanent home. In a recent case in Quincy, Ill., an infant was taken sick with croup, and a practitioner of Christian science, a Mrs. Hinckley, was called in and made a diagnosis to the effect that it was a mistake to call the child ill, on the contrary it was perfectly well. An hour and a half later when the mother took the child from its cradle it was dead. No regular physician was called in until it became necessary to have a burial certificate.

The mother was not a heartless woman, and is said to have been distracted with grief at the death of her babe. But the result did not seem to remove her faith in Christian science, which, in the case of an infant, makes the mother believe that by exercise of a strong will she can throw off the illusion which appears to effect the little one under the guise of croup, measles, or scarlet fever. Public sentiment in Quincy is greatly aroused, and it is not at all unlikely that a criminal charge will be brought against "Dr." Hinckley.

There have been some recent cases in the courts where the criminal charge of rape was under consideration, and the question to be decided was, whether the prosecutrix could be asked if she had voluntarily had previous sexual connection with one of the defendants. In both of these cases, one in Indiana and the other in Michigan, it was held that such a question was proper, but would not have been if it had referred to any other person than the defendant.

The general reputation of the plaintiff can be testified to, but no specific acts of unchastity with third persons can be inquired into.

THE Chautauqua College of Liberal Arts (The American Academia) begins its summer session of 1889 on July 5, continuing until August 16. Profs. J. T. Edwards and W, C. Gorman, of Chamberlain Institute, Randolph, N. Y., and A. C. Langdon, of the Military Academy, Macon, Mo., give instruction there in chemistry and physics. Mr. A. C. Boyden, of the Bridgewater Normal School, Mass., lectures on chemistry and physics to teachers in Normal Hall. Dr. W. G. Anderson, of the Adelphia Academy, Brooklyn, has teachers' classes in calisthenics, and gives normal instruction in physical development. Mr. W. W. White gives lessons in "memory training," which he announces as without "obsurd claims," and adds "no secrecy." Dr. Eliza M. Masher lectures on the physical development of women.

The Polyclinic.

PENNSYLVANIA HOSPITAL.

RHEUMATIC FEVER.

LONGSTRETH presented a young man, aged twenty-three, salesman by occupation, suffering from rheumatic fever. There was a history of rheumatism in his family, his father being a sufferer from it, and his mother having heart disease. Five years ago he had a slight attack, and a year later a much severer one. The present attack had been induced by exposure. When admitted to hospital his joints were all swollen, and a high fever prevailed. Auscultation disclosed a double cardiac murmur, aortic and mitral. Lungs were negative, bowels constipated. He was given ten-grain doses of salicylic acid every hour, but without effect—neither the temperature nor the swelling in the joints being reduced. He was then placed on acetate of potassa, ten grains, and bicarbonate of soda, twenty grains, every two hours, which also proved to be of no avail. Finally, the iodide and bromide of potassa were given, ten grains of each for a dose every four hours, from which very satisfactory results were obtained. The joints were smeared with blue ointment.

This patient, a woman, who works out when she is able, presented upon admission some evidences of typhoid fever. The wedge-shaped area of redness at the apex of her tongue was distinctly marked. Her temperature was 104.8°. The abdomen was resonant and irritable, and patient complained of having much diarrhœa. The evacuations were chunky, with hard, fecal masses, but were not of the characteristic yellow color. Patient also vomited, which ceased upon giving bismuth. Micturition was difficult. I ordered her bismuth in ten-grain doses every two hours, also quinine to reduce temperature, and a milk diet. A cold flaxseed poultice was applied to abdomen. Hot poultices increase the temperature 1° to 2°, which was to be avoided in this patient. I continued the quinine, in three-grain doses, night and morning, and gave enough bismuth to keep the stool black, so as to allay the irritation of the mucous membrane of the intestinal tract.—*Longstreth.*

In a case of miscarriage Longstreth took occasion to make some pertinent remarks relative to the after-treatment in such cases. The patient before the class was a Polish woman, who had ten days before given birth to a stillborn child, which had died two days before delivery. The after-discharge was very offensive. Regarding the disposition to investigate the cause of it the doctor said: "Do not enter the womb in this condition with fingers or instruments, unless it be positively known that there is something there which must be removed by mechanical force, in the exercise of which there is always more or less harm committed. The organ should be disinfected with a solution of permanganate of potassa, the injection of which should be continued until the solution returns clear and pink in color, which indicates that the part has been cleansed. The peroxide of hydrogen is also a good injection, being an active agent in the destruction of pus. Like the other, its injection should be continued until it returns clear and without foaming." The patient had a prolific crop of head lice, for which the doctor ordered the application of a soda solution in the form of a poultice.

Hunt recommends in the administration of ether a previous examination of the throat. He cited a case in which death almost occurred from hypertrophied tonsils, which fact had not been observed previous to placing the patient under ether. He was nonplussed as to the cause of the strangulation until an examination of the throat was made.

MEDICO-CHIRURGICAL HOSPITAL.

NON-BACILLAR PHTHISIS.

A RECENT case has well exemplified the apposite remark that what is called consumption is sometimes simply molecular death. The subject was a man well up in his fifties, whose constitution had been enervated by many years residence in India, and further broken by a succeeding season of privation and chronic malarial toxæmia. In this condition he attempted to earn his living at an occupation which kept him upon the street constantly during business hours, especially upon days when the weather was such as to confine business men to their offices. One memorable day he spent upon the street during a heavy cold rain. This was the finishing touch. He contracted a bronchitis, which persisted through his life, and ended it in fourteen months. There was a gradual destruction of his lung tissue by cirrhosis, with the formation of bronchiectases; constant cough, rarely hæmoptysis; never hemorrhages, night sweats, intestinal flux, or bronchorrhœa. His temperature was taken many times, though not regularly, and never exhibited a rise above the normal, but was often somewhat subnormal. Œdema of the ankles existed for six months previous to his death. Feebleness of the heart and dyspnœa were prominent characteristics of the case; the former being manifested for several years previous to this final illness. No bacilli were ever found in the sputa, which, moreover, always dried when exposed. Always a delicate eater, he showed little more than his usual fastidiousness when ill. Death took place finally from œdema of the lungs—itself a consequence of heart failure and anæmia.

Now, this was evidently a non-bacillary consumption of the lungs. The causes of his malady and the reasons for his death are evident. The man's stock of vitality was exhausted; the springs of life had been licked up by the pitiless sun of India; the little remaining strength pilfered by the malarial intruders. He stood with the outward seeming of a man, but with his vitality exhausted. The symbol ordinarily used to represent this condition is that of the oak, fair without but rotten at the heart, which waits but the first rude blast to fall in ruin. But if the shock of a tempest does not come to overthrow the oak, its destruction is no less certain, though the end comes later. Man is not often, if ever, constructed with the

nice balancing manifested by the deacon in building his famous "One Hoss Shay." Some part is pretty sure to be weaker than the others, and here is where death begins. The lungs are frequently the most vulnerable part, whether from their exposed situation, their proneness to disease, or other cause, and the beginnings of molecular death are oftenest here. An exposure to cold and wet occurs, a catarrh ensues, the vital forces are insufficient to carry the disease process through its phases to a restoration of the normal state; the lymph spaces become blocked by detritus, the connective tissue congests, thickens, contracts, the air-cells disappear; and as sacculi form, the secretions lie in them until they decompose and still further injure the weakened tissues. Molecular death is here progressing, without any need of the tubercle bacillus or any of its congeners to explain the phenomena.

Men seem to think it necessary to give an excuse when death occurs. While each is ready to acknowledge that to all death comes, soon or late, yet in the plans for life the end is but rarely taken into account. We are perpetually tearing down our barns to build bigger; and death rarely fails to surprise us when he comes. The truth of this is shown in the extent to which the bacillar theory of consumption has been carried. Not content with showing the causative relation between this microörganism and one form of phthisis, we must needs go so far as to claim that all forms are due to it; losing sight of the fact that man will die and the mourning cortege will go along the sad path to the cemetery, even if every disease-producing germ, every toxic agent should be blotted out of existence.—*Waugh.*

JEFFERSON HOSPITAL.

REMOVAL OF THE ASTRAGALUS.

A BOY was brought into the clinic for trouble with his right ankle. The tissues of this part were enlarged, spongy, and perforated by sinuses from which a large amount of offensive pus escaped. After an Esmarch bandage had been applied to the leg, the sinuses were laid open at several points down to the bone so that thorough examination could be made. Barton intended, in case evidences of extensive and dangerous destruction from sarcomatous or tubercular infiltration presented themselves, to amputate above the ankle. The amount of damage however did not warrant this procedure, but he entirely removed the astragalus, which was hollowed out to a mere shell, curetted thoroughly all the diseased tissues, cleansed the parts with an antiseptic solution, inserted a drainage tube and put the leg to rest with a tin splint. A plaster bandage will shortly be applied.

ABSCESS FROM LIGATURE.

Barton, in cutting down on a small abscess of the scrotum, found a silk ligature which had been applied some time previously, and which instead of becoming encysted had set up irritation.

EXTRA-GENITAL SYPHILIS.—Dr. Ernst Feibes, of Aix la Chapelle, reports an unusual case of extra genital syphilitic infection. The patient presented the characteristic eruption in the left popliteal space as well as on the palmar and plantar surfaces. There were no phenomena of disease in the mouth and throat nor upon the hairy scalp, nor was there any enlargement of the inguinal glands. Judging by the kind and appearance of the eruption, the infection must have occurred four or five months previously. Syphilitic infection was most strenuously denied, both by the patient and his brother, the latter being also a physician.

A critical examination revealed no evidence of chancre of the penis, nor, as stated, was there any swelling of the inguinal glands. But in the right axilla there was discovered a gland the size of a filbert. The cervical glands on the left side were scarcely perceptible, but on the right they presented themselves in the shape of a hard knotted cord. The maxillary glands on the right side were also considerably enlarged, while on the left they were simply infiltrated. This condition of things led to the opinion that the initial lesion must be sought for on the right side of the oral cavity, or somewhere about the right side of the head. Still, in and about the mouth there were no scars, the tonsils were of equal size, and nowhere could there be found any defect.

But upon the skin of the right cheek there was found an indurated pimple about the size of a split pea, which under ordinary circumstances would be considered a simple efflorescence of acne. And now, under close questioning the patient remembers that usually he shaves himself; that whenever he goes to the barber's shop he invariably carries his own razor, but never his shaving brush; that, according to his distinct recollection, several months ago he was accidentally cut at the designated spot, but of course paid no further attention to it; that the wound had festered for some time and finally left the pimple, still visible; that previous to that accident there had been no glandular swelling such as is now apparent; that his brother, the doctor, had regarded it as simply acne, and had even touched it with nitrate of silver.

The diagnosis was now made; the pimple is the remains of the primary chancre, and the shaving brush unquestionably was the carrier of the infection, the same as it is in cases of barber's itch.

The symptoms in this case disappeared promptly by the internal use of one grain of protiodide of mercury daily, and by covering the affected skin with *emplâtre de vigo.* The patient is now undergoing *Fournier's traitement successif*, and has since remained free from any untoward symptoms whatever.

The Times and Register

A Weekly Journal of Medicine and Surgery.

New York and Philadelphia, August 3, 1889.

WILLIAM F. WAUGH, A.M., M.D., Editor.

REPRESENTING THE
PHILADELPHIA MEDICAL TIMES.
THE MEDICAL REGISTER.
THE DIETETIC GAZETTE.
THE POLYCLINIC.

PUBLISHED UNDER THE AUSPICES OF THE
AMERICAN MEDICAL PRESS ASSOCIATION.

Address all communications relating to Editorial or Subscription business to THE MEDICAL PRESS COMPANY, LIMITED, 1725 Arch Street, Philadelphia.

Address all communications relating to Advertising to THE MEDICAL PRESS COMPANY, LIMITED, 9 East 17th Street, New York.

IN developing our plan for a journal which shall be truly cosmopolitan, we have found it advisable to seek the assistance and collaboration of prominent physicians in each of the great cities of the United States. In pursuance of this object we are happy to announce that Dr. Simon Baruch has assumed charge of the New York Department. Dr. Baruch practised for fifteen years in a country district in South Carolina, and for the past ten years has resided in New York; where he has become well known as an active worker in the societies, and holds several hospital appointments. Dr. Baruch has thus rendered himself familiar with the practical work of both the country and the city physician. He has given special attention to the subject of hydrotherapy, and especially has endeavored to extend the use of this method among practising physicians; thus disassociating it from the old-fashioned "water-cure" and the modern special hospital. In this good work he has the hearty coöperation of his colleagues in THE TIMES AND REGISTER.

As a further step in the same direction, Dr. I. N. Love has assumed the editorial charge of all matters emanating from the State of Missouri. Dr. Love needs no introduction. His contributions will need no signature for any of those who are familiar with his work in the *Weekly Medical Review* and elsewhere.

We have delayed the consummation of this part of our scheme until the meeting at Newport was held and the July number of THE DIETETIC GAZETTE was through the press. We will soon be prepared to give a full list of the gentlemen who have honored us by associating themselves with our work.

With the next issue we add to our combination the *American Medical Digest*, of New York; a journal now in its eighth volume, and which has been most ably edited by Dr. Lester and his collaborators. The name of *The Digest* will be continued as the head of a department in THE TIMES AND REGISTER, and we trust that we may retain the active coöperation and good-will of its editorial staff.

Annotations.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

THIS Society is second only in importance and numbers to the American Medical Association, to which it is auxiliary and subordinate. It is essentially a working society, the sessions for scientific discussion lasting during each of the three days from 10 A.M. to 5 P.M. The days are given to scientific work and the evenings to social pleasure. No ethical or other extraordinary business ever enters into the discussions, such matters being entirely in the hands of committees, whose decisions are final and not debatable. The annual meeting this year is to be held at Evansville, Indiana, September 10, 11, and 12. The President, Dr. Geo. J. Cook, of Indianapolis, and Dr. A. M. Owen, of Evansville, the Chairman of the Committee of Arrangements are hard at work in behalf of the meeting.

A cordial invitation is extended to the medical brethren east of the Alleghanies to come out to the meeting. We have assurances from Drs. Dudley S. Reynolds, Arch. Dixon, Wm. Porter and I. N. Love, all of them ex-Presidents of the association, that this will probably be the banner meeting.

INEBRIETY AS A DISEASE.

THE subject of inebriety is attracting much attention at the present day from members of both the bar and of medicine, on account of the many important medico-legal aspects of the question.

As might be expected, the members of these two professions are inclined to view the subject from different points of view, owing to their different studies, and, therefore, reach diverse conclusions.

We believe that inebriety is a disease, but it is a disease which in most cases can either be avoided or acquired. In this respect it differs from the great majority of other ills which afflict mankind, and which are acquired ignorantly. Again it differs from others in the fact that its accompaniments and consequences are so baneful to the patient's fellow beings. It is in fact a disease *sui generis*.

Dr. Parrish, of Burlington, N. J., in an article on the Medical Jurisprudence of Inebriety, cites several cases in which there was an absolute inability to avoid drink, and as soon as the patient began to indulge he lost all knowledge of right and wrong and committed acts for which a sane person would do penance behind the bars. Similar instances have been recorded by others, and there is no doubt that many an inebriate, innocent of wrong, has been condemned to imprisonment or death for crimes committed whilst under the influence of alcohol. This class of drunkards, however, is very small, and the peculiar condition is receiving so much attention that similar legal mistakes must grow less and less common.

But we think that such a conclusion as Dr. Parrish reaches, cannot be sustained. "Inebriates should not be punished for acts committed while in a state of involuntary unconsciousness any more than are somnambulists or epileptics." This conclusion ought to be admitted in those exceptional cases in which the patient, or criminal, is from the first destitute of will power to abstain from the act, but in those cases in which the man knows that if he begins drinking he is likely to lose control of his actions, or in those cases in which men drink for the express purpose either of committing some criminal act or of so obtunding their reason that they may be ready for any lawlessness, we think the violators ought to be held responsible. The line ought to be drawn at the start, between ability or non-ability to resist the taking of alcohol.

Of course this is difficult, but everything connected with the subject is difficult, and probably always will be; and to make no distinction whatever in cases of inebriety would be to offer a premium on drunkenness and crime.

ANTI-PASTEURISTS.

IN speaking of an anti-Pasteur meeting in London, the *Medical Press* notes that while all agreed in their opposition, the objectors based their action upon distinct and antagonistic grounds. One considered muzzles the true cause of hydrophobia, although the enforcement of a muzzling order is invariably followed by a decrease in the number of recorded cases. A reverend Bishop contended that muzzles were useless, as they did not prevent dribbling of saliva. An alleged physician aired his belief that no such disease existed in man; the symptoms being due to nervous prostration. The *Press* goes on to speak of the "striking ignorance of the subject and no less striking indifference to accuracy" shown by many of the speakers. Thus far, the course of the anti-rabists has been upon lines strictly parallel to that of the anti-vaccinationists; and while there are undoubtedly some intelligent persons who do not accept Pasteur's deductions, the probability is that the opposition will finally be confined to a similar collection of unreasonable cranks.

Letters to the Editor.

MEDICATING AIR.

I NOTE your query as to the desirability of medicating air—"if the air is already pure, why medcate it?"—and think you may not have fully understood the object of my invention. This will be more fully explained in the extract which I enclose from *Cassell's Magazine*.

The idea of charging air supplied to buildings with antiseptic vapor is due to Mr. Burroughs, who has recently applied it to the ventilation of the premises, Snow Hill Buildings, Holborn Viaduct, where it can now be seen at work. The method of ventilation adopted is that of Mr. B. F. Sturtevant, introduced into England from America, where it is already largely employed. It consists in forcing fresh air from the purest available source outside, into the building by means of a rotary fan or air-blower. This fan can be driven by the waste steam from an engine on the premises, and at the same time heated by the steam. The temperature thereby given to the air is regulated by the simple device of mixing cold air with it in the proportions required. Flues or pipes convey the warmed air to the various pipes of the building where it is required; and the outflow from the pipes is controlled by simple regulators. Thus both the temperature and supply are under the complete control of the persons in the building. The advantages of forcing fresh air into the building under a slight pressure are that cold draughts from without are excluded, and the vitiated air is forced outwards by every available opening. In a building supplied with electric lighting apparatus, the waste steam of the dynamo engine is utilzied to warm and ventilate it at the same time. By inserting in the flue trays porous material such as cotton waste, soaked in the eucalyptia (the essence of eucalyptus globulus), pinol or any other antiseptic and aromatic extract of a volatile nature, the air in its passage to the various rooms of the building, or it may be to any one particular room, is impregnated with antiseptic vapor. For hospitals the system is evidently well adapted, and very complete, since it may include the electric light, warming and antiseptic ventilation in one process. For private individuals suffering from diseases of the breathing organs, it is also equally applicable, whether in the office or the home.

What I wished to do was to devise an apparatus for supplying filtered medicated air to hospitals, and thus to do away to some degree, with the necessity of using inhalers. The volatile antiseptic is to be charged into a glass dropper, which at the same time regulates the drops which fall upon the sponge or gauze in the main air pipe. The air is thus charged with the antiseptic, say pinol (the volatile essential principle of the pinus pumilionis) or eucalyptia (the volatile essence of the eucalyptus globulus) or any other volatile medicament can be employed. The advantages of this method over those commonly in use, are:

1. The air is filtered, a matter of much importance in such a smoky atmosphere as that of London.

2. It can be warmed to an exact temperature, or a uniform temperature can be maintained without difficulty by regulating either the supply of steam or by causing part of the air only to flow through the box of steam pipes.

3. The air can be medicated to any degree desired by means of the dropper referred to.

S. M. BURROUGHS.

LONDON, ENG.

PHLEGMASIA DOLENS.

I HAVE not chosen this subject because I expect to evolve any new theory or propagate any new doctrine as to the source of its first nucleus in the human economy. While it comes with the inflammation and the pain, and usually presents certain characteristics at certain stages, yet there are also certain differences that might lead us to believe that there might be different origins in different cases. For instance, some cases appear to harden and enlarge, as circumscribed as if from some initial point, while others appear to be mostly in and about the glands, while, again, a whole limb is so involved that we must conclude it is a constitutional disease. I have had some experience with this disease, and I will set forth in part or wholly the origin and course of three cases that impressed me differently.

The first was Mrs. C., at Maineville, O. Since her last parturition, nine years previously to my seeing her, one of her legs (I think the left) had been swollen and painful. I gave her some liniment, the principal of which was solution iodo-brom. calc. comp. and oil of sassafras in alcohol equal to both, and to use it freely, from which she experienced much relief. But she soon after moved down on the river, where she remained two years. During this time she had ague and large hemorrhages, it being her climacteric period. When she returned she soon came under my cognizance. Her malaria returned several times while she was gone, but did not after her return. When I saw her again she was very hydræmic, and after each hemorrhage became worse, until she could hardly see on account of the swollen face, and the dropsy became general, and it looked as if she had only returned to die among her friends. She told me that she had taken iron in every form, and it always disagreed with her stomach, and it was impossible to take it. But by insisting, I had her take mur. ammonia in mur. tinct. ferri to saturation, twenty drops, three times a day, in simple syrup for a couple of months, by which she was greatly benefited, as her hemorrhages became ordinary, and her size reduced and strength materially increased. But the rebellious stomach assisted her repugnance to iron, and I had to drop it. I then resorted to malt, which, at least, held her up until waning nature had time to reinvigorate and assert her predominance. Mrs. C. has again become a busy housekeeper, with a reasonable degree of health.

On the 6th day of July, 1885, I was called to Mrs. P. in her third parturition, and though not through the first stage she was full of dread that in some way this would be a finality for her. The last months had been rather miserable, and she being weak it had worn much on her mind, but with usual severe pains she passed a natural labor; so we congratulated ourselves that her fears were unnecessary, though other fears combined with these, as a near relative died the day before with sequelæ of confinement. About the fifth day, she said she had rheumatism in the left leg and arm, particularly the lower limbs. I suspected the nature of the case, although the hardness did not come for two days, and then only in the legs. I therefore gave full opiates and used embrocations of liniment, and a little later hot fomentations of flannels, hops, etc. In the course of ten days the pain had largely subsided, but left the swollen and tense hardness that is so characteristic of phlegmasia.

Remembering that when a boy on the farm the older brothers used mullein (verbascum thapsus), boiled in cider vinegar, on the horses to reduce swollen parts, that I conceived must be in some degree similar to this (and my prejudice being somewhat disarmed since it was recommended for consumption), I ordered a trial of it on this patient, and the result was most gratifying, as in a few days' use by fomentations she was comparatively comfortable, and the limb reduced nearly to the size of the other, and the tissues nearly as soft. She made a good recovery.

February 1, 1889, I arrived at the bedside of Mrs. W. in her fourth confinement. I found no unusual case, but she was unaccountably depressed. When all was over her mother-in-law told she had had a great foreboding that she would not get well.

I assured them her condition was very good, and I could not see any reason why she should not get along all right, only as the left nipple was gone, the probability was she would have some trouble with her breast. I took the precaution to try to abort the secretion of milk, but did not succeed well, perhaps because the nurse was careless and the patient was impatient, and exposed herself by getting out of bed the third day and walking across the floor, as I learned afterwards. The 13th, I was called back to find her with pain in the superior portion of the left lung and pleura. Auscultation developed crepitus; cough and expectoration were present, the pulse 108, and temperature 101½.

She had been chilly, as she said, for several days. I also found the left breast swollen and tender. I proceeded to give Dover powder and antifebrin alternated.

In two days I dropped the antifebrin and gave her ammonia instead, with quinine. On this mode of treatment she improved for a week, when she informed me she would not take any more medicine, contrary to my opinion and advice.

But after she had passed two nights she recalled me. I again gave the Dover powder and quinine and poulticed the breast with flaxseed, and used liniment on her side below the breast, as she complained of external pain. Three days later I lanced the breast, which gave her some relief, but the very next day the thyroid and parotid glands were also swollen.

The swelling was so sudden and so severe that she appeared about to suffocate from the tenseness of the swelling and complications; pulse was 130, temperature 104. Believing now there must be some blood poison from this phase of things, I had counsel, which confirmed this opinion, and also thought I could do no better than push the Dover with tonic and stimulant treatment. But even then she began to complain of her left leg, but there was no hardness or swelling in the tissues at any point, and but little tenderness, neither did it show any other symptom of inflammation. About two days after consultation there was considerable amelioration in all symptoms except the size and hardness of the parts, with the sense of suffocation, pulse 110, temperature 102. I cast about for something else to reduce this, besides liniments, embrocations, and hop fomentations, etc., and thinking I had a case of phlegmasia out of the common order I ordered mullein and vinegar fomentations, which produced the most happy result wherever applied to any hard and tense tissues, subduing the swelling and hardness in from twenty-four to forty-eight hours on the throat and afterwards on the arm and axilla, and the case progressed to a speedy recovery. I believe we have not arrived in our pathology, at a definite conclusion, as to the source of this disease, but it looks a little humoral in part at least.

The points in the first case are its hydræmic character and tractableness to the blood builders (so called). In the second and third cases the forebodings before confinement, also the quick reduction of the hardness and swelling of the tissues incident to this disease by the fomentations of the mullein and vinegar, when liniments, hop poultices, etc., were of so little value in these cases, and then the third case had its own peculiar different course. The attack of the left lung and pleura and the tendency of the inflammation to glands and surrounding tissues in the superior part of the body on left side, and the internal inflammation with the external, and the cough and expectoration, continued to the last.

I base these conclusions on the treatment for No. 2 and 3, when the pain was controlled by the opiate, the inflammation was held in check and the fomentations of mullein and vinegar succeeded best in bringing natural size and softness of the parts involved.

B. F. LUDLUM, M.D.

The Inquirer.

IN answer to an inquiry, we would state that the *Journal of Homœopathics*, devoted to the philosophy of homœopathy, is published at No. 19 Broadway, New York.

DR. CARHARTT'S prescription for summer diarrhœa, upon page 282 of THE TIMES AND REGISTER, should probably read as follows:

℞.—Acidi salicylici . . . . . gr. xxx.
Cretæ preparat . . . . . gr. x.
Glycerin . . . . . ʒij.
Aquæ rosæ . . . . . ʒxiv.—M.
Sig.—Fluidrachm every hour for a child one year old.

I SEND you per mail to-day a plant known to the country people by the name of the "water weed," I would like to know through THE TIMES AND REGISTER its true name. The common people use it as a specific in poisoning by rhus toxicodendron. They bruise and apply the stem and claim it to be indeed, and in truth, a positive specific.

R. H. C. RHEA, JR.
WAVERLY, KY.

[The plant sent for analysis came to hand. Water weed belongs to hydrocharidaceæ (frog's bit family); species, anacharsis canadensis. But the plant I received is not water weed, it is probably sagittaria variabilis, belonging to the water-plantain family. The absence of flower and fruit renders it difficult to classify.—J. M. A.]

WILL you publish an article in THE TIMES AND REGISTER on the mode of extracting the liquid recommended by Brown-Séquard, for the renewal of life, and oblige, A SUBSCRIBER.

[See page 275 of this journal for July 20.]

"WHAT are your charges, Doctor?"

"Three dollars a visit."

"Well, we don't want you to come on a visit, but just to stay ten or fifteen minutes."—*Puck*.

THE TECHNIQUE OF HYDRO-THERAPEUTICS.

BY SIMON BARUCH, M.D.,
NEW YORK CITY.

THE absolute necessity of an exact technique in the application of water as a remedial measure is unfortunately not appreciated by the profession, and its neglect is undoubtedly a cause of the failures which have operated in preventing the more general adoption of hydro-therapeutics by the practitioner.

Water is so simple, so readily obtainable, and so easily applied that it would seem an unnecessary refinement of therapeutics to enlarge upon the methods of its application. On the other hand, too, the empirical hydropaths and water-cure doctors have divided and subdivided their procedures into numerous baths and douches, etc., each one infallibly adapted to certain conditions.

It shall be our aim to steer between the Scylla of indifference and the Charybdis of overaction; to simplify these methods and instruct the general practitioner in such hydropathic procedures as his common sense will enable him to apply under the guidance of physiological and pathological principles.

The first step in this direction is the appreciation of the fact, that while there is no slight-of-hand or mystery in the hydropathic method, there does exist an absolute need for precision in the application of water, simple and universally applicable though it be.

A few illustrations from our clinical experience will impress this lesson more forcibly than the simple statement.

Some weeks ago one of the house physicians of one of our metropolitan hospitals informed the writer that the cold-bath treatment of typhoid fever had been inaugurated in his institution. Inquiry regarding the method adopted, elicited the fact that the patient was wrapped in a wet sheet, and ice water was poured from a sponge over the entire surface of the sheet, until the temperature was decidedly reduced; a reduction of five degrees had been noted. The prognosis made by the writer, that the woman would die under this unphysiological management, was verified in two days. Failure in the case is attributable to the fact that refrigeration was the chief aim of the treatment, whereas the success of the hydriatic management of typhoid fever rests upon the principle that the refreshing influence of cold water upon the innervation is the true indication. The latter is fulfilled by promoting reaction *during the bath* by friction of the entire body.

As this subject will be enlarged upon in future articles, this brief reference must suffice.

That the necessity for precision is well understood, however, by some of our metropolitan hospital physicians, was made evident to the writer by the receipt of a request from one of the attendants at Bellevue Hospital to aid him in instructing his house staff. A series of rules was formulated and written down by the house staff of two divisions, which will doubtless ere long bear rich fruit in the saving of life and comfort.

Within the past two weeks the writer has had occasion to suggest intestinal irrigation in two cases of summer diarrhœa of infants. Finding the treatment painful and inefficient in these cases, inquiry elicited the fact that in one case the attendant (who is an accomplished physician) had cut off the lower third of a Nélaton catheter and converted the upper into a drainage tube by cutting three eyeholes into it. Is it surprising that the introduction of such a tube was painful, and irrigation through it was ineffective? One thorough irrigation, in accordance with the technique laid down on page 32 of the DIETETIC GAZETTE (April 1, 1889, number), changed the entire aspect of the case. In the other case referred to the attendant had used a No. 8 French rubber catheter, had placed the child in the dorsal position and attempted to irrigate with a Davidson syringe.

The tube doubled up in the rectum, its upper end was too small to connect with the syringe point and failure was the inevitable result of this neglect of proper technique. The reverse of this picture is contained in the following extract from a letter read by the writer Dr. Chas. Schaim, New York City. "I have successfully managed a desperate case of summer diarrhœa in a child 18 months old by following out implicitly the principles of treatment laid down by you in your monograph on the subject, published a year ago" (*Medical News* July 7, 1888). "The case was one of a severe type with high fever, muco- purulent and bloody dejections and vomiting. I feel that I owe you a debt of gratitude for the assistance derived from studying and following the principles laid down in your paper etc. A few days ago a masseur applied to the writer for work, stating that he was quite familiar with hydriatic procedures. Being asked to describe the dripping sheet process, he said that a sheet should be dipped into cold water, and thrown over the patient who should rub himself with it as well as he can with the aid of the attendant. This specialist had entirely lost sight of the important elements of the technique, which are the use of a linen sheet, a thermometer for exactly estimating the temperature and the necessity for the patient remaining entirely passive, while the attendant applies active friction outside of the sheet.

In future articles the technique of hydro-therapeutic processes, their effects and indications will be fully discussed, in fulfilment of the pledge made in our last issue.

HYDRO-THERAPEUTIC ANTISEPSIS.

Laparotomy in the newborn was done by Dr. Stolpinsky in Kasan, Russia. The child, normally developed and strong, suffered from irreducible umbilical congenital hernia. Sixty minutes after birth, under chloroform, an incision three centimetres long was made on the left of the linea alba, one coil of intestine being adherent to the back, a portion of the latter was resected and dropped with the coil, the remainder was dissected away, the peritoneum stitched by catgut, etc. No antiseptics were used, instruments, etc., being boiled and retained in distilled water, the field of operation cleansed with water and soap.—*Int. klin. Rundschau.*

HYDRO-THERAPEUTIC MANAGEMENT OF TYPHOID FEVER.

The non-medicinal hydriatic treatment of typhoid fever is warmly commended in a recent paper read by Prof. Fuerbringer before the Berlin Medical Society. The mortality in 155 cases was 16, viz., 10 per cent. We agree with Prof. Fuerberger in regarding this a very low mortality, considering the type of cases received in the Friedrichshain Hospital. Whosoever casts a glance, says Prof. Fuerbringer, upon the most unfavorable imaginable quality of our typhoid cases in general, whoever has seen how many patients are really brought into the institution to die, will be able to understand why I regard a mortality of 10 per cent. a favorable one, indeed, one that approaches the most attainable minimum. The principal point to which we desire to direct the attention of our readers is the treatment. No abortive remedy was used, neither calomel nor naphthalin, which he regards as useless, medicinal antipyretics only in very limited and selected cases; good nourishment with sherry, opium and camphor in threatening asthenia. "The majority of the patients received a methodical, mostly mild, and individualizing bath treatment, *less as an antipyretic than as an excitant and dietetic (for refreshment of the nervous system, cleanliness, stimulation of the appetite, combating of hypostases, etc.)* To report to you the result of these therapeutic measures, I regard as the chief duty of my life. I may to-day point out to you that there is scarcely another medical director of a large division who is as favorably situated regarding the exclusion of all statistical fallacies, etc."

We desire to emphasize the estimate placed by this renowned clinician upon hydratic measures, and, especially, the purposes for which he applies them, because we have again and again dwelt upon the importance of recognizing in the bath treatment a farther reaching influence than a mere antipyretic would exercise. So long as this bugbear of pyresis, and its inevitable therapeutic sequence antipyresis, continue to dominate the minds of the profession, the revolution in fever treatment, which has already brought comfort and life saving to thousands, will be retarded.

It shall be our aim to further this beneficent cause by truthful portrayal of clinical results from all available sources.

SUSPENSION TREATMENT OF TABES CASES.

The popularity of this measure appears to be seriously threatened by reports of various misadventures, some of which have resulted fatally, and others afford us a warning which should be heeded. Self-suspension, especially, cannot be too severely condemned. The *Berl. Klin. Wochenscer.*, of July 8, contains a report of a case confirming Bernhard's experience in two cases. Bernhard's cases presented loss of consciousness, dilated pupils, convulsive movements, and complete amnesia of all that had happened. Dr. Bruns reports a patient, who after being suspended not quite five seconds, ceased to speak, turned pale, his pupils dilated and he became unconscious. He was at once let down, consciousness returned, with-

out realizing his surroundings. This being his first suspension, Bruns thought that the carotids had been compressed. The head gear was removed, patient again suspended with the same result. In one hundred and fifty other suspensions no similar results were observed.

We may observe that in a very large number of suspensions at the Montefiore Home we have experienced no unpleasant result. Our rule, however, is, that suspension must not be done by the nurse without supervision of one of the house staff.

BATHS IN VARIOLA.

During the epidemic of variola in Dorpat, 1887–88, Dr. Alex. Hartge (*Wiener Med. Presse*, No. 25) resorted to one or two daily baths, of 88°–92° F., after giving a laxative in the prodromal stage.

In confluent cases the baths were especially useful, until the temperature begins to subside spontaneously. When administered early, they influenced the course of the disease in a most remarkable manner. The papules and little knots shriveled and atrophied; the vesicles dried quickly and the stage of pustulation and suppuration was prevented together with the fever accompanying it. There being no pustules, no scars remained. If the pustules were developed before baths were resorted to, the latter helped very little.

The patients felt subjectively quite well; the tension, pain and itching in ano ceased after the bath, they slept more quietly and appetite was improved. Even children and nurslings bore the baths well.

Book Reviews.

THE PHYSIOLOGY OF THE DOMESTIC ANIMALS. A Textbook for Veterinary and Medical Students and Practitioners. By ROBERT MEADE SMITH, A.M., M.D., Professor of Comparative Physiology in the University of Pennsylvania. Four hundred illustrations; pp. 675. Price, cloth, $6; sheep, $6.75. Philadelphia: F. A. Davis, Publisher, 1889.

In spite of the almost innumerable books on medicine and allied subjects, it is singular that up to this time there should not have been a work in English treating of this subject. We welcome Prof. Smith's volume the more warmly, therefore, because it is a sort of pioneer.

The subject of the physiology of the domestic animals is of interest and value, not to the physiologist alone, or to the veterinarian, but also to the general practitioner, for these studies and experiments are the best means we have at present of reaching accurate conclusions with regard to similar processes in the human being.

The author first treats at some length of General Physiology, beginning with the properties of cells, their origin, modifications, and the development of tissues and organs. Cellular physics is next considered, the physical processes, properties in cells and their mechanical movements.

He finally discusses cellular chemistry. Under Special Physiology he gives, first, an interesting section on the foods used by the domestic animals, with elaborate analyses of the various constituents of their substances.

In logical order Digestion is next considered, and the different organs and fluids that take part in this act.

The blood, respiration, excretions and secretions, special senses, reproductive processes, all receive careful attention and able treatment.

Prof. Smith is happy in his arrangement of the matter, and also in the way in which he has considered each topic. For instance, in taking up digestion, he begins with the simplest form known—the amœba—and from that traces the development of the process through ascending grades of the animal kingdom till he has reached the complexity of the mammalian apparatus.

This is his method of discussing each of the main subjects, and it is a method greatly to be commended for clearness and worth.

The book is profusely illustrated with good cuts, some of them colored. The illustrations are mostly reproductions of figures in previous works of various kinds, since Prof. Smith has not assumed, we believe, to set forth much that is altogether new, but rather to give in a readable form the results of value collected from the many investigators in this department.

MANUEL DE MÉDECINE. DE J. F. MALGAIGNE. Professor de Médecine Opératoire à la Faculté de Médecine de Paris, Membre de l'Académie de Médecine, etc. Neuviéme Edition par Léon Le Fort, Professeur de Clinique Chirurgicale à la Faculté de Médecine de Paris, Membre de l'Académie de Médecine. Second Partie: Opérations Spéciales, avec 434 figures intercalées dans le texte. 12mo. pp. 871. Paris: Ancienne Librairie Genner Bailliere et cie. Felix Alcan, Editeur, 1889.

The author states it is unusual to preface the second volume of a work; it is equally unusual to review one in this order. Our excuse is that the first volume is not yet at hand. The work is such an exceptionally elegant one, and of such exceptionally high merit, that it seems like a deprivation to retain it from notice for an unnecessary time. Neither author needs an introduction to American students. Malgaigne is as familiar to us as Gross or Pancoast; Le Fort, his able successor, has left charming recollections of his personality by his visit to the Ninth International Congress in Washington, and those who had not previously known of him soon learned to see a master in this brilliant writer and lecturer. The volume in hand deals with the special surgical operations, and is certainly the most complete that has ever been seen by us. The first part of the volume is devoted to operative procedures upon the eye, and it is doubtful if any special work upon this surgical division gives the accurate and detailed delineations of the many different procedures that may be practised to attain the same end. This is indeed a praiseworthy feature throughout the entire book, While Le Fort has in many instances practised methods of his own invention to secure certain results, with a modesty that is not usual in medical authors, he does not give such procedures undue prominence, nor does he forget those practised by others in which attainments equally good have been claimed. It is rare to find such a mélange upon individual methods, and it must be difficult for an author not to slight those opera-

tions which are left unpracticed for those only chosen by individual preference. Yet Le Fort has accomplished this. How? A part of the solution can surely be found in the statement he makes in the preface: "No operation or method of procedure has been recommended that has not been first practised by me upon the patient, or its feasibility been demonstrated upon the cadaver in the dead-house." It would then seem that apart from fancy he tries all, that none which deserve it shall not have the prominence to which their value may entitle them. This is evidence, itself, of a broad mind, and shows that the author cannot be likened to that woman described by George Meredith: "She could conceive of but two possible opinions upon any given subject—her own and the wrong one." After the eye and its appendages, the nose, ear, mouth, throat, thorax, abdomen, rectum and anus are each in turn considered, and are followed by the genito-urinary diseases in man and woman, special chapters upon the diseases and operations upon the uterine appendages, extra-uterine pregnancy and the Cæsarian operations being the closing ones of the book.

If there be one part of the volume which deserves mention above another it is such of it as is devoted to plastic surgery, and this is not a small part. Text-books usually devote so little attention to this important part of practice, that what is given is so inadequate to the needs of particular cases that it is practically worthless. The student, during his term of tuition, is fortunate if shown a half dozen cases in which this interference is practiced. The teacher after giving a few fundamental principles which underlie this all important part, usually dismisses the subject by saying the practitioner must exercise his own ingenuity to devise such flaps as shall give the most perfect result with the least possible lasting deformity. Admirable advice! but unfortunately it is only the exceptional surgeon who ever attains to this exceptional ability. The result of all this is, that very few operators are good plastic surgeons, many avoid interference that is absolutely essential, and some operate with resulting deformities that are truly heartrending. The cause must surely be insufficient knowledge of the cicatricial changes produced and the consequent deformity by distortion and obliteration of the normal lines. The author has evidently gone to great lengths to rectify this deficiency. The matter devoted to this subject cannot too strenuously be recommended to the general reader, and it would be difficult to conceive of any one who would not clearly understand something of the cosmetic art after finishing the study.

He has recognized the wonderful aid that diagrams give to the elucidation of this often intricate procedure, and very faithfully depicts the primary incisions, transplantations, and ultimate fastenings of the flaps; in consequence the matter is so simply and vividly pictured that any novice can quickly grasp the subject. It is to be regretted that so little attention has been given to the work of the American surgeon, indeed, excepting the chapters on the diseases of women and that devoted to tubage of the larynx, scarcely an American name can be found in the book. In the chapter devoted to intubation the author quotes largely from the paper of M. J. Stern, read at the Washington Congress, and which is ascribed to Stein.

Too much praise cannot be given to the illustrations throughout the work, they are most copious and it has evidently been the aim that where it was possible to elucidate a subject with a drawing, it was inserted. It is no exaggeration to state that the serial drawings of many operations described are so complete that the procedure is perfectly intelligible without referring to the text. This is particularly true of the parts devoted to cosmetic surgery, of the illustrations themselves, it may be said, they are accurate and of the highest merit, another rarity in surgical text-books. He earnestly hopes the work will meet with a continuance of the favor in which it has been held, and the strenuous efforts that have evidently been made to perfect it must surely destine it to continue its position among the foremost surgical text-books of the age. M. J. S.

The History of Education in Florida. By George Cary Bush, Ph.D. Pp. 57.

The History of Education in Georgia. By Charles Edgeworth Jones. Pp. 154.

History of Higher Education in South Carolina, with a Sketch of the Free School System. By Colonel Meriwether, A.B. Pp. 247.

History of Higher Education in Wisconsin. By William F. Allen and David E. Spencer. Pp. 68.

It is well that this series of monographs relating to the growth of educational facilities in the different States, and the effects produced by this increase, has been taken in hand at the present time. Much information that can now be gained by exploiting old records, old newspapers, and various other sources, may either, through accident or the lapse of time, shortly be impossible to acquire. At once, therefore, is the proper moment to collect from these different and transient sources their individual contributions and form them into a complete and permanent whole. The results are valuable, not only at the present time, but will also inspire gratitude in the heart of the future historian.

The History of Education in North Carolina. By Charles Lee Smith.

This belongs to a series of contributions to American Educational History, edited by Prof. Herbert B. Adams, Ph.D., of Johns Hopkins University.

The author furnishes a pamphlet of 177 pages, and shows by his work that he has spared neither time nor patience to make his record as valuable as possible.

Out of the 400 or 500 cases of typhoid fever in Philadelphia, a large part of them are in the Kensington district. Nineteen new cases in this district has led the Board of Health to urge the City Council to discontinue the pumping station at Otis Street wharf, Delaware River. Since the recent resumption of these works there has been a twenty-five per cent. increase in the death-rate.

Pamphlets.

Directory of the Class of '88 of the Jefferson Medical College.

Radical Cure of Hernia; by Thomas W. Kay, M.D., Scranton, Pa.

Twenty-fifth Report of the Trustees of the City Hospitals, Boston, 1888.

University of Pennsylvania, Catalogue of Department of Medicine for 1889–90.

Remarks on the Unpleasant Effects of Sulphonal, by J. P. Crozier Griffith, M.D., Philadelphia.

Clinal Observations on the Action of Sulfonal-Bayer, published by W. H. Schieffelin & Co., New York.

Annual Announcement and Catalogue of the College of Physicians and Surgeons, Baltimore, 1889–90.

Catalogue of the Albany Medical College, Medical Department of Union University, Session of 1888–90.

On Some Mild Measures in the Treatment of Intra-nasal Hypertrophies and Inflammations, by W. H. Daly, M.D., Pittsburg, Pa.

Where the more radical measures are inadmissible for any reason, Dr. Daly advocates blood depletion, especially in hypertrophies of the nasal walls. This method is almost painless, and he has gained from it excellent results.

Inebriate Asylums and Their Work, by T. D. Crothers, M.D.

The author holds that inebriety is a disease, not merely a habit, and must therefore be treated as a disease. He gives an interesting account of the origin of inebriate asylums and the difficulties they encountered. He concludes that there is little hope of doing much good, unless the patient commits himself to the absolute control of the hospital authorities. There is slight dependence to be placed on moral suasion alone with a man who has lost all his will power.

Digestive Ferments. A Consideration of their Nature, Action, Quality, Dosage and Incompatibilities, with notes on Clinical cases. Compiled from current literature by the scientific department of Parke, Davis & Co., 1889, 148 pages.

The subject of dietetics and aids to digestion has now become such an important one that any contribution to our knowledge in that direction is of inestimable value to the profession. Messrs. Parke, Davis & Co. have presented in their brochure an exhaustive compilation of the results of recent investigation on the two great ferments, pepsin and pancreatin, thus producing a concise and convenient grouping of the latest literature on these aids to digestion.

Spinal Localization in its Practical Relations, by Charles K. Mills, M.D., Philadelphia.

This paper, added to Dr. Mills' excellent one on Cerebral Localization, makes a valuable contribution to the important subject of Localization. The first part of the paper is devoted to general considerations, in which he mentions the operations which have so far been performed for spinal affections, gives notes on cases of focal spinal lesions, with autopsies, discusses the feasibility of operating for spinal tumors, intraspinal hemorrhage, caries and angular curvature, and for intractable neuralgia affecting nerves close to their origin. In the second part he takes up The Facts and Rules of Spinal Localization, and treats the subject in a lucid and easy style, and in such a manner as to show not only that he is thoroughly conversant with what he has undertaken, but also that it is worthy of the title "Practical" which he has given it.

The Relation between Trophic Lesions and Diseases of the Nervous System, by E. C. Seguin, M.D.

Dr. Seguin classes co-called "trophic lesions" under two heads, first, a class which includes cutaneous ulcerations, falls of hair and nails, altered appearance of nails and hair, articular changes, deep eschars, necrosis of digits, and most of the lesions observed in the hollow viscera lined by epithelium. He considers these to be proved not to be trophic disturbances, but capable of being prevented by appropriate means. In the second class are enumerated all those lesions in which extraneous or traumatic causes cannot be shown to act. These he considers to be truly trophic in character, but as to the mechanism of origin he admits nothing is known.

Gleanings.

It is a pleasure to record the names of the following New York physicians who give their services this year in aid of "The Tribune Fresh Air Fund. They examine all children that the Fund proposes to send into the country to see that they are free from contagious diseases. These physicians are: Drs. C. C. Vinton, W. J. Hall, F. E. Hopkins, Annie S. Daniel, George Williamson, John P. Toland, M. E. Herrick, Gertrude B. Kelly, M. M. Vinton, Sarah A. French, Andrew L. Barrett, and Charles L. Lang.

Dr. Mashkovski measured the chests of 275 consumptives and the same number of healthy persons (212 males and 63 females in both cases), with a view of ascertaining whether it has any bearing on the etiology of phthisis. The result of his observations are: the circumference in consumptives is 0.03 c.m. less; the upper anterior posterior diameter is the same, the middle anterior posterior diameter is even larger (0.16 c.m.), the thoracic coefficient (the relation between the lower transverse diameter and that of the anterior posterior) is 1 c.m. less in phthisis. While on an average the difference in measurement between healthy and consumptive persons is insignificant, the difference between consumptives of the first stage (well preserved) and those of the second stage (disease highly developed) is very considerable. Dr. M. concluded that there is no indication of the existence of a typical chest peculiar to consumptives, and, therefore, an abnormal chest cannot be regarded as predisposing to phthisis, and the diminution of some of the diameters in consumptives is a consequential condition following the development of disease.—*Vratsch.*

Continuous Secretion of Gastric Juice with Decrease of Free Acid Salts. (Secretio Continua Anacidata.)—Dr. Puritz reports the following case of dilated stomach. The patient complained of pain and heaviness under the ensiform cartilage, which increased after meals, and more so towards evening. He walked with a stooping gait, and was compelled to lie with face downward. Had nausea and frequent inclinations to vomit; severe belching, heartburn and lack of appetite. On percussion from sixth rib downward—tympanitic sound; on palpation of abdomen—felt like cushion filled with air. The stomach could hold without any inconvenience to patient about three litres of water. On introducing the sound, gastric juice could be obtained at any hour of the day, the stomach not having been irritated by the entrance of food or any other mechanical cause. The gastric juice was present in the morning, on an empty stomach, and was also obtained half an hour after the stomach was thoroughly washed. The analysis of the juice has shown the presence of free acid salts in quantities less than normal (0.067–0.159 per cent.). The urine contained chlorides in excess which confirmed and complemented the observations of Drs. Gluzinski, Jaworski, Rosenthal, Sticker and Grudzew, who, experimenting on cases of increased quantities of chlorides in gastric juice, discovered the existence of an inverse ratio between the free acid salts and the amount of chlorides in the urine. —*Vratsch.*

The Modern Waste of Health.—Our elaborate code of by-laws for the suppression of holiday recreations can still be circumvented by the resources of opulence, and the well-known hopelessness of any other expedient has stimulated a race for wealth which does not hesitate to attain its object at any risk of social or sanitary consequences. The number of infants which the superstition of the Ammonites sacrificed to Moloch is a mere trifle compared with the multitude of children now devoted to a far more cruel fate by being literally drudged to death in crowded factories to enable a millionaire to save a few dimes on his weekly pay-roll and add a few per cent. to the exorbitant rate of his yearly profits. In times of general scarcity the market has been drained of its scant supplies by speculators trying to coin gain from the distress of their fellow-men, and risking after all, to be foiled by the decay of their hoarded stores or their destruction by fire or flood. Quack nostrums, which not one intelligent man in a hundred would privately hesitate to pronounce infinitely worse than worthless, are sold by ship-loads and car-loads to disseminate disease and the seeds of the stimulant-vice, and the saints who contribute thousands to insure the theological soundness of the Quaggalla Hottentots do not care enough for the physical health of their own countrymen to whisper a word against the lawfulness of the infamous traffic.—*From "The Wastes of Modern Civilization," by* F. S. Oswald, M.D., *in the Popular Science Monthly for August.*

Massage of Abdomen and Lumbar Region as a Diuretic.—Dr. Polubinski reports his observations of massage on the abdomen and lumbar region made with a view of ascertaining its physiological action on the kidneys. The subjects upon whom he experimented were healthy persons, and they received the same quantity of food. The experiment commenced at 12 (noon) when the subjects (ten in number) urinated, and the urine thrown away. The urine of the twenty-four hours was collected in different vessels as follows: First portion from 12 to 2 P.M. (in massage days: dinner, half hour; massage, half hour, and one hour rest); second portion, from 2 to 4 P.M. (massage, half hour; one and a half hour rest), and from 4 to 12 of the following day. When the abdomen was massaged the quantity of urine during the first two hours was considerably increased, so much so that the whole quantity of the twenty-four hours, as compared with that on non-massage days was notably increased. The amount of urine between 12 and 4 P.M. was three times that on non-massage days for the same period. Even the third portion of the urine (from 4 P.M. till noon) was on the increase, insignificantly, though. Along with the increase in quantity the solids urea and urates were increased. When massage of lumbar region was made the quantity remained the same on non-massage days, but the solids, urea and urates, considerably increased during the whole twenty-four hours.—*Vratsch.*

Medical News and Miscellany.

St. Joseph, Mo., has a new medical journal.

Lemon-juice relieves pruritus ani very quickly.

Dr. Boenning has removed to 538 North Sixth Street.

The Chicago *Medical Examiner* has suspended publication.

Dr. E. A. Wood, of Pittsburgh, is said to be seriously ill.

The Attica sleeping wonder is getting tired of it, and is coming around.

Efforts are being made to stop the sale of fraudulent Apollinaris water.

Dr. Thomas H. Andrews spends the summer at The Chalfonte, Cape May.

Dr. Leffmann found arsenic in the stomach of Mrs. Glynn, of Scranton.

Dr. Timothy Newell, of Providence, is the defendant in a suit for divorce.

Dr. Ernest Laplace, of New Orleans, is visiting Dr. W. H. Pancoast at his Elberon cottage.

A patient died in Bellevue Hospital of angina ludovici, following the extraction of a tooth.

For hyperæsthesia of the intestinal mucous membrane there is no remedy equal to acetate of lead.

The St. Louis *Weekly Medical Review* has been enlarged to the size of the Times and Register.

Dr. William C. Roney, a prominent physician of Pottstown, died Tuesday night, aged sixty-five years.

This has been an exceptionally healthy summer for Philadelphia, as shown by the record of interments.

The Minnesota Board of Health have decided to send a man bitten by a rabid cat to Pasteur for treatment.

After a while nothing will be open in this city on Sunday except the question whether life is worth living.—*Times.*

Surgeon-General Hamilton says that great progress in sanitary reform has been made in the Southern cities.

A peculiar and fatal affection of the bowels prevails at Rarden and Otway, O. It is attributed to the drinking water.

July 25 was Donation Day at the Hospital of the Good Shepherd. The receipts were insufficient to cover the expenses.

Dr. Lawborn, of New York, offers $200 in prizes for essays on the dragon-fly, and its employment as a destroyer of mosquitoes.

The meeting of the Pennsylvania State Medical Society has been postponed until next June, when it will be held at Pittsburgh.

Dr. Church, resident physician at the Williamsport Hospital, is enjoying a two weeks' vacation travelling in the Western part of the State.—*Press.*

Jordan Blair, of Montrose, Pa., is said to have amputated his own leg with a jack-knife, and to be on the road to recovery.

I. I. Mapes, a graduate of Columbia College, New York, has taken the Edinburgh University medal for proficiency in the study of anatomy.

Dr. James Bloomfield has resigned from the resident staff of the Philadelphia Hospital and will remove to Georgia to practice.—*Press.*

The Upas tree is another exploded phenomenon; the ground about and under it being as salubrious as any other locality, for plants and animals.

Newark is also on the war path for purer water; the Jersey courts having decided that Passaic may use the river for a sewer as long as it likes.

Dr. H. M. Frist, of Wilmington, has been appointed one of the Demonstrators of Chemistry at the Jefferson Medical College, Philadelphia.

A Renovo girl became insane just after taking a glass of ice-water; and her physician very unnecessarily attempts to explain the *modus operandi.*

The chemist of the New York Board of Health recommends ventilation of the subways, as 866,000,000 cubic feet of gas escapes yearly into the streets.

The faith-curers are having a good deal of fun poked at them; but not any more than they deserve. Ridicule is the only weapon to point at nonsense.

Frank Jones, of Columbia, was afflicted with liver complaint, and at the suggestion of a friend he took salpetre as a remedy. He took an overdose and died.

Three female physicians have been arrested in Sayreville, Middlesex County, for practicing without a diploma. The charge was made by another female practitioner.

Dr. J. L. Baker's family, of West Chester, were at table the other night when the connection of the electric light burned out, emitting sparks which set fire to the tablecloth.

Dr. W. Reynolds Wilson, son of the late Dr. Ellwood Wilson, has resigned from the resident staff of the Philadelphia Hospital in order to take charge of his father's practice.—*Press.*

Dysentery is prevailing in Howard County, Md., and adjacent sections of Baltimore County. The disease extends to all ages alike. A number of deaths have already occurred.—*Times.*

The Philadelphia Board of Health decided to permit the Fairmount bath-house to remain on condition that it shall be moved seventy-five feet nearer the dam and bathing restricted to the ebb tide.

The Luzerne County Medical Association will meet at the Lake Hotel, Harvey's Lake, Pa., on August 7. Harvey's Lake has taken its place as one of the most favored mountain and lake resorts of the country. The beautiful scenery, pure water, cool breezes, and comfortable Lake Hotel make a combination of attractions equalled by few resorts.

VALERIANIC ether, in pearls containing five minims, proves a very useful stimulant for anæmic women, subject to fainting fits and attacks of pain in the region of the solar plexus.

A HUNGARIAN woman in Reading is said to have been bitten by a copperhead, and immediately gave birth to triplets. That beats Brown-Séquard; America is still ahead, and the country's safe.

SURGEON DUNCAN, of the steamship "Colon," who didn't have yellow fever, although quarantined for it, has at last succeeded in getting married. His fiancee was also quarantined while he was ill.

A PHILADELPHIA lady allowed her physician to treat her for fifteen years for heart disease, though she refused to accept the diagnosis. She died, an autopsy was held, and the doctor was right.

A VERITABLE valley of death is said to exist in the Yellowstone Park, where animals, even as large as the bear, are asphyxiated. This is said to account for the disappearance of game from the Park.

DR. SEGNITZ urges the New York Board of Health to recommend a law prohibiting the marriage of consumptives. Let us go a little easy, and first compel the disinfection of sputa, as more effective and easier to enforce.

DR. TALCOTT, of the Middletown Lunatic Asylum, is said to have found that base-ball playing has an excellent effect upon his patients. We are unable to say whether Dr. T. is a homœopathist or not; but suppose so from the above.

THE architect employed by the Board of Education has made an alleged reply to the report of Dr. Taylor. There is a general cleaning up in progress, and it is probable that the nuisances will be abated before the fall term opens.

EACH German regiment is to have a chiropodist attached to it. There is no question as to the importance of keeping the soldier's feet in order, but it would be better to compel the regular surgeon to learn the art of the chiropodist.

FOR SUMMER DIARRHŒA.—

℞.—Tinct. hydrastis . . . . . ℥j.
Potas. carbonat. . . . . ℥j.
Syr. rhei aromat. . . . . ℥vij.—M.
Sig.—Half ounce every four hours.—*Waugh.*

THERE is not much use in giving the sulpho-carbolates by the mouth in summer complaint when the affection is mainly in the lower bowel. The salt should then be used by enema—ten grains to one or two ounces of any mucilaginous liquid.

OATMEAL water has become a popular summer beverage in many of the Philadelphia manufactories. Once accustomed to this drink, the most inveterate beer-guzzler will not exchange it for any alcoholic drink, if he is working in great heat.

IF all the public school buildings reported by Medical Inspector Taylor are as defective as the report indicates, the only time a large portion of the school population of this city can be considered at all safe is during the vacation season.—*Times.*

DR. ALEXANDER R. BLAIR, after an illness of several weeks, died at his residence in York, aged sixty-two years. The York County Medical Society held a meeting and adopted appropriate resolutions.

THE Marine Hospital Bureau has information that the report of the existence of dengue fever at Fernandina, Fla., is false, and the report of yellow fever on the northeast coast of Mexico is also denied.—*Record.*

THE Society of Science, Letters, and Art, of London, has awarded to Ephraim Cutter, M.D., LL.D., a gold medal for his papers recently read before it, entitled: The Relations of Medicine and Music, Cleaned Whole Wheat, and Hygienic Drinks.

THE course upon physiology at the Medico-Chirurgical College will be given this winter by Dr. Samuel Wolfe. Dr. Wolfe attracted much attention as a fine speaker last summer, when he gave the Address in Obstetrics at the Pennsylvania State Medical Society.

THE Director of the Royal Elizabeth School, in Berlin, Prof. Waetzoldt, has entered a strong protest against the practice of allowing young girls of doubtful musical ability to spend hours at the piano; to their own physical detriment and the torture of their hearers.

AN actress is said to have reduced her weight fifty pounds in twenty days. Her method of diet is nearly as comprehensive as that of Caryl Carne, in Blackmore's romance, Springhaven. She lives on water and one orange per day, and takes three Turkish baths weekly.

DR. RANDLE has made a report to the Board of Health upon the typhoid fever, which in all essential particulars verifies the view taken in our editorial. He points out that the large number of cases reported from Kensington includes those in the large hospitals, coming from all parts of the city.

THE law of heredity goes on silently enforcing itself without trial or sentence, from generation to generation. Its forces gather and break, unknown to the ordinary observer, building up and tearing down human life, with a certainty that knows no change or shadow of turning.—*Journal of Inebriety.*

DR. JOHN B. ROBERTS has been elected Professor of Surgery at the Woman's Medical College of Philadelphia; taking the place hitherto filled by Dr. W. W. Keen. Dr. Roberts has always been a consistent friend of the lady physicians; and by his election the Faculty gains a cool and skilful operator, a popular and experienced teacher.

THE crying need for a general divorce law is shown by the asserted fact that a Philadelphia doctor is a good, law-abiding citizen at home, but if he crosses the Hudson River into New York, he is a bigamist, with the State Prison staring him in the face.

This is all wrong; especially as it tends to raise a distinction between the legal and the right, and thus lessens the respect for law, which is the foundation of civil liberty.

Dr. D. W. Harrington, a prominent Lockport physician, accidentally took an overdose of morphine to relieve neuralgia in the head. Three doctors saved his life with an electric battery after all other means failed.—*Press.*

The disinterested parties who are anxious to have water brought to Philadelphia from the upper Delaware, above Trenton, are probably not aware that when this water was analyzed, some time ago, it proved to have more organic matter in it than that of the Schuylkill. This was probably of vegetable origin.

The American Association of Obstetricians and Gynecologists will hold its next annual meeting at the Burnet House, Cincinnati, O., in the rooms lately occupied by the Military Order of the Loyal Legion, on Tuesday, Wednesday and Thursday, September 17, 18 and 19, 1889. No formal invitations will be issued to non-members, but the Association hereby extends a cordial invitation to such members of the profession wherever resident as may feel interested, to attend the meeting and participate in the proceedings. The papers and discussions will embrace subjects pertaining to obstetrics, gynecology and abdominal surgery. By order of the President.

William Warren Potter, *Secretary.*

The Faculty of the College of Physicians and Surgeons of Baltimore held a meeting to fill the vacancies created by the deaths of Professors John S. Lynch and Oscar J. Coskery, and the retirement of Professor A. B. Arnold, who has retnrned to San Francisco. Prof. Thomas S. Latimer was transferred to the chair of principles and practice of medicine and clinical medicine; Prof. Charles F. Bevan to the chair of principles and practice of surgery and clinical surgery; Prof. J. W. Chambers to the chair of operative and clinical surgery, and Prof. George H. Rohé to the chair of obstetrics and hygiene. Prof. Thomas Opie will continue as professor of diseases of women and dean of the faculty. To fill vacancies created by these transfers new professors were elected as follows: Prof. Henry Sewall, of the University of Michigan, to the professorship of physiology; Dr. George J. Preston to the professorship of anatomy, with the diseases of the nervous system as a clinical branch of instruction. Dr. N. G. Keirle was elected as lecturer on legal medicine, in addition to his demonstrations in pathology; Dr. George Thomas as lecturer on diseases of the throat and chest; Dr. G. A. Liebig, Jr., of Johns Hopkins University, lecturer on medical electricity, and Dr. J. H. Branham, demonstrator of anatomy. Drs. L. F. Ankrim, Frank C. Bressler and F. G. Moyer were appointed assistant demonstrators, and Dr. R. G. Davis, prosector of anatomy. Prof. Sewall, who comes here from the University of Michigan, is an old Baltimorean, and was for several years demonstrator of biology in Johns Hopkins University. All the other appointees are residents of Baltimore. As an evidence of esteem on the part of his colleagues, Prof. Arnold was elected Emeritus professor of clinical medicine on his retirement.

Army, Navy & Marine Hospital Service.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 16, 1889, to July 29, 1889.

Steinmetz, Wm. R., Captain and Assistant-Surgeon. Now at Baltimore, Md., on leave of absence on account of disability, will, by the direction of the Secretary of War, report in person to the commanding officer of the Watertown Arsenal, Mass., for duty at that station, relieving Lieutenant-Colonel James C. McKee, surgeon. Par. 3 S. O. 166, A. G. O. July 20, 1889.

McKee, Colonel and Lieutenant. Will repair to Philadelphia, Pa., on being relieved at the Watertown Arsenal, and assume the duties of attending surgeon and examiner of recruits in that city. Par. 3, S. O. 166, A. G. O., July 20, 1889.

Robinson, Samuel Q., Captain and Assistant-Surgeon. Leave of absence for two weeks is hereby granted. Fort Hamilton, N. Y. H. Par. 11, S. O. 165, Headquarters Division of the Atlantic, July 22, 1889.

Ball R. R., Lieutenant and Assistant-Surgeon. Leave of absence granted in S. O. 87 Department of the Missouri, July 9, is extended five days. Par. 1, S. O. 167, A. G. O., July 22, 1889.

Ewing, Charles B., Assistant-Surgeon. Promoted to be Assistant-Surgeon with the rank of Captain, after five years service, in accordance with the Act of June 23, 1874; July 5, 1889.

Ball, R. R., First Lieutenant and Assistant-Surgeon. The extension of leave of absence granted, in S. O. 167, July 22, 1889, from this office, is further extended ten days. Par. 23, S. O. 169, A. G. O., Washington, July 24, 1889.

By direction of the President, the State of Arkansas, embracing Little Rock Barracks, is transferred to the Department of the Missouri. General Orders, No. 66, Headquarters of the Army, A. G. O., July 19, 1889.

Gardner, William H., Major and Surgeon. Is detailed to attend the encampment of the National Guard of the District of the Columbia, by direction of the Secretary of War, at Fort Washington, Md., from July 22, to July 29, 1889, for the purpose of giving instructions to the medical officers and hospital corps in their respective duties. Par. 1, S. O. 164, A. G. O., July 18, 1889.

Bunton, H. G., Captain and Assistant-Surgeon. By direction of the Secretary of War the extension of leave of absence on surgeon's certificate of disability granted, in S. O. 22, January 26, 1889, from this office, is further extended two months on account of sickness. Par. 1, S. O. 162, A. G. O., July 16, 1889.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service for the week ending July 20, 1889.

Vansant, John, Surgeon. When relieved to proceed to Mobile, Ala., July 11, 1889.

Mead, F. W., Passed Assistant-Surgeon. Relieved from duty as acting Chief Clerk and Attending Surgeon, and ordered to St. Louis, Mo., July 11, 1889.

Williams, L. L., Passed Assistant-Surgeon. Relieved from duty at Cape Charles Quarantine Station; Ordered to Baltimore, Md., July 10, 1889.

Kalloch, P. C., Passed Assistant-Surgeon- Granted leave of absence for thirty days, July 15, 1889.

Pettus, W. J., Assistant-Surgeon. When relieved to proceed to Marine Hospital, Boston, Mass., for duty, July 18, 1889.

Woodward, P. M., Assistant Surgeon. Granted leave of absence for thirty days, July 15, 1889.

Vaughan, G. T., Assistant-Surgeon. Relieved from duty at Boston, Mass., and ordered to Norfolk, Va., July 18, 1889.

Stoner, J. B., Assistant-Surgeon. Granted leave of absence for twenty-five days, July 15, 1889.

Geddings, H. D., Assistant-Surgeon. Relieved from duty at Baltimore, Md., ordered to Key West Quarantine Station, July, 18, 1889.

Wertenbaker, C. B., Assistant-Surgeon. Relieved from duty at Norfold, and ordered to Galveston, Texas, July 18, 1889.

Groenevelt, J. T., commissioned as Assistant-Surgeon, July 11, 1889, ordered to Gulf Quarantine Station for temporary duty, July 20, 1889.

Clinical Lecture.

SURGICAL CLINIC.

Delivered at the Medico-Chirurgical College of Philadelphia.

BY H. EARNEST GOODMAN, M.D.,
Professor of Surgery.
(Reported by JOHN W. CROSKEY, M.D, Chief of Clinic.)

GENTLEMEN: I bring to your notice two interesting cases to-day, and again call attention to the fact of the importance of attending all clinics, as a failure to see cases of disease and injury, is a loss you may never be able to make up, while didactic lectures may be shaken, with the knowledge that they may be made up from the text books we recommend to you. Surgery requires a knowledge of what our masters knew and have taught, and aside from this it requires personal observation and experience only obtained from the bedside.

The more faithfully you attend the clinics, the more cases you see and study, the sooner you will become experts and be looked up to as masters in our wonderful art.

What is the meaning of the suffix oma? Mr. Blank answers that it is a Greek termination, inseparable, which added to a stem makes words designating tumors formed as the result of morbid processes, and malignant growths of all kinds.

Now to make this knowledge of the meaning of the suffix oma useful, you must know your anatomy to get the stem; knowing your anatomy, if you will consult the charts on the walls you will see that you have a knowledge of the names of all tumors that flesh is heir to. These same remarks apply to all the prefixes and suffixes which go to make up the language of medicine and surgery.

The first case is an oma, its stem angi, meaning vessel; hence we have angioma, a blood tumor, or one caused by a morbid process in the bloodvessels.

You remember Mr. T., and how we removed, assisted by Prof. Montgomery, one and a half pounds of angiomatous tissue from his right lumbar region, extending down to his thigh. How we controlled hemorrhage by the use of Prof. Pancoast's long pins run under the tumor in various directions and surrounded by a strong ligature; how tedious the operation, because of the many bleeding points; how thoroughly antiseptic the operation was, with the constant irrigations of sodium silico-fluoride; except two or three unwashed hands that were called in later in the operation as aids; how secondary hemorrhage occurred the first night, which was relieved by pressure; how the drainage tubes got pulled out accidentally the second day; how sapræmia supervened, the fever always running down after irrigation of the wound, and being finally subdued by two daily irrigations; how firm was the union by the so-called first intention in the cut, and how now he presents himself before us to-day well, save a little inflammatory thickening under the scar near the spine.

What lessons do we learn from this case, and what mistakes did we make? It is well to tell of our mistaks, as well as of our successes. Hippocrates did so and was commended for it by Celsus. Our mis-

takes were to allow unwashed hands to handle the wound; the pins were not sterilized and their punctures were the first points of suppuration; the hemorrhagic clot should have been removed the day following its occurrence, if not at the time, and all the usual antiseptic precautions gone over again; the resident should not have pulled out the bundle of cat-gut drainage.

Now this man has gotten well in spite of our mistakes. You ask why? and I tell you that although we admit they were mistakes they were not radical ones, and the patient was also a good one for an operation. His moral tone was good, he was gentle, pleased with all that was done for him, could chew a little tobacco all through his sickness, was not too fat or too thin, good vigorous age (twenty-five years), no syphilitic taint, nor had he been exhausted by debauches. Any surgeon seeing him would say he would get well after almost any operation. I would have picked him out during the late war as a fine specimen of a man for any amputation. His internal treatment was milk punch and beef juice every four hours; the latter made from four pounds of lean beef daily; iron and quinine; with an occasional dose of antipyrin to lower the temperature, when it ran up to 103 or 104.

The second case is another oma; as it occurred upon the epithelium of the lip, we call it an epithelioma. In this case it is caused by a malignant growth. Many of you will recall Mr. S., who, about one year ago, had a wedge-shaped piece removed from his lower lip, containing a tumor which our microscopist pronounced cancer. The tumor again made its appearance in six months, when he returned to the clinic thoroughly dissatisfied with the operation. I urged another operation, which he indignantly refused, saying that a knife should never touch him again. He presented himself before you three weeks ago with a raw tumor involving the lower lip, as large as a hen's egg. Said he had been treated with salves by a Mrs. Hinkle, a drawing salve and soothing one. You remember his pallor, the offensive nature of the tumor, with dribbling of the saliva. He begged for another operation, which was done after the manner of Syme and Serre. I will recall the operation to you. The principle of Syme's operation is to leave the central part of the chin undisturbed. The incisions were from the angle of the mouth down to each side of the prominence of the chin, crossing just above that prominence, then curved in a line with lower margin of lower jaw to angles. As you will recollect, the cancer extended well up in the angle of mouth, left side. Serre's modification of taking a triangular piece from this side was followed. After the flaps were thoroughly dissected up and all the bleeding points ligated with catgut, they were then brought together with hair-lip pins, run nearly through the cut edge, but never entering the mouth cavity, and then further closure of the wound was made by black (No. 5) silk interrupted sutures.

Now, the technique of this operation was antiseptic as far as possible, and I have often told you that operations about the mouth are of necessity not always antiseptic. You will recall many severe operations in oral surgery by Prof. Garretson, made without antiseptic precautions, and all wonderfully successful. You ask why is this, and I tell you that all authors in surgery agree that wounds heal more kindly nearer the center of circulation than at a distance, and where tissues are better supplied with bloodvessels. The face is rich in bloodvessels, and wounds of the face heal rapidly, and this one is no exception to the rule, as it healed up in three days' time without a drop of pus. The only dressing used was collodion and iodoform, which is a favorite of mine for all small wounds, particularly about the face. You see there remains some little thickening at the right side of the mouth, but which is getting softer, he says. For fear this very radical operation has not removed all the cancer cells, we will suggest that he go to Dr. Walling three times a week for the continuous galvanic current; which seems to have the reputation of reducing morbid and malignant omas, and in my hands has been a benefit to the fibromas of the prostate.

PULMONARY HYGIENE.

(An Address prepared for the meeting of the Pennsylvania State Medical Society, in Pittsburgh, June 4, 1889.)

By THOMAS J. MAYS, M.D.,
Professor of Diseases of the Chest in the Philadelphia Polyclinic and College for Graduates in Medicine.

OUR power of prevention is measured by our knowledge of the causation of disease, and I trust, therefore, that I will be pardoned if, instead of following the customary plan of reviewing the science of hygiene during the past year, I shall undertake to discuss the important question of pulmonary hygiene. When we reflect that through hygienic errors of omission and of commission, the lungs are far more liable to disease than any other part of the body, and that they are the channels through which nearly one hundred thousand lives are annually sacrificed in this country on account of pulmonary consumption alone, I feel confident that you will grant me this indulgence, if, as I hope, I will be able to add something which will at least tend to increase our store of knowledge in regard to the production and prevention of this disease.

At the very outset I shall briefly consider a few points in the anatomy and physiology of the respiratory organs. The lungs are enclosed in a bee-hive shaped cavity called the chest, the sides of which are composed of ribs, muscles, and skin, and the floor of a broad, movable, and elastic membrane called the diaphragm. The lungs derive their nerve supply from the pneumogastric and the diaphragm from the phrenic nerves—the peripheral branches of both uniting in a ganglion on the abdominal portion of the vena cava. The pneumogastric is a nerve of motion and of special sensation to the lungs, and regulates the respiratory function, and on account of being the most vital nerve in the body, it plays a most important rôle in the production of pulmonary disease.

Now, it is the universal experience of the medical
